NATURE

A WEEKLY JOURNAL OF SCIENCE

"To the solid ground
Of nature trusts the Mind that builds for aye"—WORDSWORTH

150

Volume 150

JULY 4, 1942, to DECEMBER 26, 1942

LONDON
MACMILLAN AND CO., LTD.
NEW YORK: THE MACMILLAN COMPANY

DATES and PAGINATION of WEEKLY ISSUES

Serial No.	*Date of Issue*	*Pagination*
3792	July 4	1–32
3793	,, 11	33–64
3794	,, 18	65–96
3795	,, 25	97–128
3796	August 1	129–160
3797	,, 8	161–188
3798	,, 15	189–216
3799	,, 22	217–244
3800	,, 29	245–272
3801	September 5	273–300
3802	,, 12	301–328
3803	,, 19	329–356
3804	,, 26	357–384
3805	October 3	385–412
3806	,, 10	413–440
3807	,, 17	441–468
3808	,, 24	469–496

INDEX

NAME INDEX

Prof. R. I., Intuitive Knowledge, 770
G., Aldwich, L. B., and Hoover, W. H., Annals of the Astro-ical Observatory of the Smithsonian Institution, Vol. 6, 226
Jniversity of, Sir John Orr appointed professor of agriculture,
of. N. K., The Public Schools in Great Britain, 433
Physics and Chemistry of Surfaces, third edition, *review* by Prof. c K. Rideal, 730
ancis (1796–1861), 286
m, Miss Jocelyn F., Land Settlement—its Sanitary and Architural Aspects and After-War Possibilities, 571
t, F. T. (James, W. M., and), Horticultural Work on the Amaryllceæ, 232
rof. E. D., Mechanisms of Vision, *review*, 727
., appointed assistant district commissioner in the Gold Coast, 90
ical Society (Royal), Wilbur Wright Memorial Lecture by the Hon. Lord Brabazon, 15
ral Engineering, National Institute of, 87
ral Research Council: Dr. W. S. Gordon appointed director of e Compton Field Station, 148
James Gray, and Prof. F. L. Engledow, appointed members, 207
re and Fisheries, Ministry of, F. A. Secrett appointed honorary dviser on vegetable production, 288
Dudley Stamp appointed adviser on rural land utilization, 429
stry, Sir Robert Renwick appointed Controller of Communicans, 346
Robert Watson-Watt to continue as Scientific Adviser on Telemmunications, 346
Production, Ministry of. Sir Robert Renwick appointed Conller, 346
obert Watson-Watt appointed Vice-Controller of Communicas Equipment, 346
upply Council, Sir Robert Renwick to become a member of, 346
, Kenneth, and Dattan, P. A., A Russian-English Technical ctionary, 323
., An Undescribed Stage of Sarcotaces, 180
obert G., Sirius and its Companion, 572
H. G. (Michelbacher, A. E., and), Insect Fauna of Lower Calinia, 552
e Great Mughal, 600
L. B. (Abbot, C. G.,) and Hoover, W. H., Annals of the Astroysical Observatory of the Smithsonian Institution, Vol. 6, 226
r, Dr. W. A., Determination of Equilibrium Diagrams by X-Ray thods, 467
r. H., Existence of Electromagnetic-Hydrodynamic Waves, 405
erica Cables and Radio, Inc., 30-kw. Short-wave Radio Transmitter or (F. D. Webster and R. E. Downing), 52
., Growth and Development, 422
r. E. J., *death* of, 685
r. R. J. L., Dried Foods, 223
echnical Advisory Committee, appointment of a British Association Committee to collaborate with the, on Scientific Problems of Post-War Reconstruction of Agriculture in Europe, 346
p, Dr. C. B., A Water-soluble Carcinogen Derived from 3: 4-Benzpyrene, 548
George. Nova Cygni, (1942), 463
ructure of Galactic Clusters, 664
alactic Clusters in relation to the Galaxy, 740
can Chemical Society, Prize in pure chemistry of 1,000 dollars for 1942 awarded to Dr. John Lawrence Oncley, 52
an Institute of Physics, Report on the Man-Power Problem in Physics in the United States, 369
an Philosophical Society: Symposium on Recent Advances in American Archæology, 155
Franklin Medal awarded to Dr. Sylvanus G. Morley, 155
erican Society of Chemical Industry, Chemical Industry Medal for 1942 awarded to Dr. Harrison E. Howe, 372
erican Society of the History of Medicine, William Osler Medal awarded to John T. Barrett, 573
erican Society of Mechanical Engineers, Harry R. Ricardo elected an honorary member of, 687
Dr. Mulk Raj, The Old and the New in India, *review*, 131
arded a Leverhulme Research Fellowship, 150
e, Prof. E. N. da C., Goethe's Science, *review*, 275
deliver the Newton Tercentenary Lecture of the Physical Society, 628
ewton and the Science of his Age, 628, 655, 700
o-Soviet Scientific Collaboration Committee, 285
us, Dr. W. Rogie, Scattering of Light, 741
yal, Dr. Andras, Foundations for a Science of Personality, *review* by J. Drever, 418
en, Ruth Nanda (planned and edited by), Freedom, its Meaning, view by Prof. A. D. Ritchie, 100
J., Temperature Control, *review* by J. H. Awbery, 727
D. Waldemar, Yellow Fever in Brazil, 573
Sir Edward, Dried Foods, 223
s (British), Royal Institute of, First general statement of conions of the Reconstruction Committee, 410
se, Colonel Sir Charles, Future of the Population of Great itain, 140
A. G., Electrical Production of Bullet-proof Steel, 298
Armstrong, Dr. E. F., Mineral Resources and the Atlantic Charter, 202
    Minerals, Old and New, from the Sea, 453
    The Humanities of Chemistry, *review*, 475
    The Story of Explosives, *review*, 561
    Biochemistry—General and Particular, *review*, 589
    A Dyer Imparts his Knowledge, *review*, 618
Arnot, Dr. F. L., Time and the Universe, a New Basis for Cosmology, *review* by Dr. G. C. McVittie, 308
Arthur, Prof. J. C., *death* of, 116
Arts, Royal Society of, Series of lectures on Agriculture To-day and To-morrow, 543
Aschoff, Prof. Ludwig, *death* of, 315; *obituary* by Dr. J. D. Rolleston, 398
Ashby, Prof. A. W., Efficiency and Output in Agricultural Systems, 723
Ashby, Dr. Maurice, awarded a Silver Medal of the Royal Society of Arts, 51
Ashby, W. R., The Slide Rule Cursor, 379
Ashe group of associated companies, Dr. W. E. Gaunt appointed research director, 149
Ashhurst, W., Scientific Films and their Use in the Teaching of Physics, 691
Asiatic Society (Royal), (British Council), the East India Association, and the India Society, Meeting to celebrate the centenary of the birth of Akbar, the Great Mughal, 600
Aston, Dr. F. W., International Table of Stable Isotopes, 515
Astronomical Association (British), to be accommodated in the rooms of the Royal Astronomical Society, 427
Astronomical Society (Royal), Symposium on the Structure and Rotation of Galaxies, 169
    Geophysical discussion on The Figure of the Earth, 339
    Meeting in celebration of the tercentenary of the death of Galileo and the birth of Newton, and the bicentenary of the death of Halley, 483
Asundi, Prof. R. K., and Singh, Nand Lal, Selective Excitation of Spectra by the High-Frequency Discharge, 123
Atkins, Dr. R. J., Mineral and Vitamin Requirements and the War-time Dietary, 125
Australian Association of Scientific Workers, conferences on the use being made of scientific men in Australia, 494
Avery, A. G. (Blakeslee, Albert F., and), Nine Strikingly Diverse Types in *Datura Stramonium* with Location of their Determiners in a Single Chromosome, 238
Avery, G. S., Growth and Development, 421
Awbery, J. H., Temperature Control, *review*, 727
Ayyangar, G. N., Genetics of the Sorghums, 663

BACH, Dr. S. J., and Williamson, S., Formation of Urea in the Mammalian Body without Participation of Arginase, 575
Bacharach, A. L., Mineral and Vitamin Requirements and the War-time Dietary, 125
    A Central and Scientific Technical Board, 383
Baddeley, Dr. G., Steric Promotions and Inhibitions of Polarizations, 178
Bagenal, Hope, Practical Acoustics and Planning against Noise, *review* by N. Fleming, 193
Bagnall, Dr. R. S., awarded a Leverhulme Research Fellowship, 150
Bai, K. S., Scattering of Light by Liquids, 741
Bailey, Dr. E. B., Crater Lake, *review*, 3
Bain, F. W., appointed chairman of a Committee on Synthetic Rubber, 150
Baker, Prof. Alfred, *death* of, 542
Baker, E. C. Stuart, Cuckoo Problems, *review* by Dr. F. H. A. Marshall, 221
Baker, Frank, Microbial Factors in the Digestive Assimilation of Starch and Cellulose in Herbivora, 479
Baker, F. C., *death* of, 116
Baker, H. G., A Red Colouring Matter from the Green Leaves of Spinach Beet, 689
Baker, Dr. John R., The Scientific Life, *review* by Prof. John L. Myres, 164
    Scientific Literature for Enemy Prisoners of War, 408
Baker, Dr. J. W., Energy-Level Treatment of Reaction Data, 551
Baker, Wilson, Structure of 'Diphenylene', 210
Balfour, F. R. S., Early Botanical Explorations of David Douglas, 89
Baly, Prof. E. C. C., *obituary* of Prof. J. N. Collie, 655
Banay, Dr. Ralph S., Alcoholism and Crime, 428
Banner, E. H. W., An A.C. and D.C. Peak-Factor Meter, 401
Bannerman, J. M., appointed a member of the Forestry Commission, 632
Barber, H. N., Localized Chiasmata in *Fritillaria Meleagris*, 26
Barclay, O. R., Feeding of the Common Toad, 376
Barcroft, Sir Joseph, Dried Foods, 223
Barcus, L. F., Rotating Sectors in Stellar Photometry, 436
Barker, B. T. P. (Russell, Sir E. J., Kay, Dr. H. D., Ogg, Dr. W. G.), Messer, Malcolm, Browne, Geoffrey, Garner, F. H., McMillan, J. A., Wilks, T. Nellist, Holmes, Dr. E., Orrell, W. R., and other Experts, Farming Handbook, *review*, 618
Barker, Dr. J., Dried Foods, 223
Barker, Dr. S. G., *death* of, 315; *obituary*, 397
Barlow, K. E., The Discipline of Peace, *review* by R. Brightman, 219
Barnard, Eric, Dried Foods, 223
Barreto, Dr. João de Barros, Public Health in Brazil, 631
Barrett, John T., awarded the William Osler Medal of the American Society of the History of Medicine, 573
Barrett, Sir James W., General and Social Biology, 124
Barron, Dr. Harry, Modern Synthetic Rubbers, *review* by Dr. W. J. S. Naunton, 751
Bartlett, T. L., London Gulls, 765

Bartley, S. Howard, Vision, a Study of its Basis, *review* by Dr. Katharine Tansley, 166
Baruch, Bernard, appointed chairman of a committee on Synthetic Rubber Production, 207
Barzun, Jacques, Darwin, Marx, Wagner : Critique of a Heritage, *review* by Prof. A. Wolf, 72 ; (Prof. Macgregor Skene), 150
Bassindale, R., Marine Fauna of Bristol Channel, 435
Basle, University of, honorary doctorate of the medical faculty conferred on Prof. Eugen Pittard, 232
Batco, S., *obituary* of Prof. Joseph Paczoski, 85
Bate-Smith, Dr. E. C., Dried Foods, 223
Batten, Dr. G. E., *death* of, 116
Battle, Helen I., Development of the Liver in the Salmon, 26
Bawden, F. C., Potato Virus Diseases, 476
Baylis, Dr. H. A., *obituary* of Mr. C. C. A. Monro, 84
Baynes, Dr. H. G., The Hippocratic Myth, *review*, 247
Beadle, G. W. (Tatum, E. L., and), Biochemistry and Genetics, 552
Beeson, C. F. C. (Mathur, R. N., and), On the Biology of the Parasites of the Shisham Defoliators in the Punjab Plantations, 552
Beirne, Bryan P., Biology of the Larch-Shoot Moth, 435
Bellamy, H. S., The Book of Revelation is History, *review*, 363
Bellis, E., appointed agricultural officer, Kenya, 488
Benedict, Ruth, Race and Racism, *review*, 192
Benham, W. E., Encouragement of Research in Industry, 235
Benjamin, M., and Jenkins, R. O., Autoelectronic Emission from Single Crystal Metal Points, 295
Bennett, Viscount, awarded a Silver Medal of the Royal Society of Arts, 51
  Peter Le Neve Foster lecture on Empire Relations, 370
Bennett, Wendell Cl., Archæology of the Andean Field, 157
Benton, W. A., *obituary*, 50
Bergmann, Dr. Ernst, Mineral Resources and the Atlantic Charter, 202
Bergmann, Prof. Peter Gabriel, Introduction to the Theory of Relativity, *review* by Prof. W. H. McCrea, 359
Berkeley, E. and C., North Pacific Polychæta, chiefly from the West Coast of Vancouver Island, Alaska and Bering Sea, 609
Berliner, Dr. Arnold, *death* of, 229 ; *obituary* by Prof. P. P. Ewald, 284 ; *obituary* by Prof. Max Born, 284 ; *obituary* by F. I. G. Rawlins, 315
Bernal, Prof. J. D., Science and the War Effort, 263
  obituary of E. A. Nahum, 341
  to deliver the first Sir William Bragg Memorial Lecture of the Chemical Society, 488
Bernal, Prof. J. D., and others, The Public Schools in Great Britain, 351
Berrill, N. J., Growth and Development, 421
Bertram, Dr. C. K. Ricardo, Death of St. Peter's Fish in Lake Huleh, Palestine, 58
Bertram, Dr. G. C. L., awarded the Bruce Memorial Prize, 52
Bessey, O. A., Growth and Development, 422
Besterman, Theodore, Union List of Periodicals in British Libraries, 637
Beveridge, Sir William, Social Insurance and Allied Services, 753
Bevin, Ernest, Functions of Works Managers, 229
  University Students and Military Service, 732
Bhargava, M. P., and Nayer, A. N., Bagasse for the Manufacture of Paper and Board, 88
Bibby, Cyril, Nomenclature of Biological Movement, 405
  An Experimental Human Biology, *review* by Dr. D. L. Gunn, 562
Bidder, Dr. G. P., Causes of Intertidal Zonation, 158
Biffen, Sir Rowland, Auriculas, 237
Bilmes, L., A Rheological Chart, 432
Binns, H. R., appointed senior veterinary research officer, Palestine, 207
Birch, A. J., and Robinson, Sir R., Long-chain Acids containing a Quaternary Carbon Atom, 553
Birkinshaw, Dr. J. H., and others, Notatin, an Anti-bacterial Glucose-aerodehydrogenase from *Penicillium notatum* Westling, 634
Birmingham, Social Survey Committee, Nutrition and Size of Family, Report on a New Housing Estate, 1939 (Prepared by M. S. Soutar, Dr. E. H. Wilkins and Dr. P. Sargant Florence), *review*, 475
Birmingham, University of, Prof. F. H. Garner appointed to the chair of Oil Engineering and Refining, 545
Bissell, Thomas A., and Shidle, Norman G., Motor Vehicles and their Engines, fifth edition, *review*, 74
Black, D. A. K., McCance, Dr. R. A., and Young, W. F., Function of the Kidney in Dehydration, 461
Black, Miss E. I., Austerity Thinking, *review*, 417
Blackburn, Dr. Kathleen B. (Harrison, Prof. J. W. Heslop), and Bolton, Ethel, Vitamin C and Chromosome Number in Rosa, 574
Blackburn, S., Middlebrook, W. R., and Phillips, H., Oxazoline and Thiazoline Rings in Proteins, 57
Blackman, Dr. M., and Born, Prof. M., Raman's Theory of Specific Heat of Crystals, 55
Blaikie, Lennard, *obituary* of D. B. Mair, 261
Blair, Dr. G. W. Scott, 'Tack' and Sticky Materials, 160
  Design and Standardization of Rheological Apparatus, 271
Blair, Dr. G. W. Scott, and Coppen, F. M. V., Mechanism of Sensitivity Changes of Sense Organs, 580
Blair, Prof. Thomas A., Weather Elements, revised edition, *review* by Dr. C. E. P. Brooks, 728
Blakeslee, Albert F., Growth and Development, 421
Blakeslee, Albert F., and Avery, A. G., Nine Strikingly Diverse Types in *Datura Stramonium* with Location of their Determiners in a Single Chromosome, 238
Blakeslee, A. F. (Overbeek, J. van, Conklin, M. E., and), Artificial Culture of Datura embryos, 435
Blewett, M. (Fraenkel, Dr. G., and), Biotin, B$_1$, Riboflavin, Nicotinic Acid, B$_6$ and Pantothenic Acid as Growth Factors for Insects, 177
Bodle, Ralph R., United States Earthquakes, 1939, 239
Boell, E. J., Growth and Development, 422
Bok, Dr. Bart J., Distribution of the Stars, 459
Bolliger, Dr. A., Experimental Production of a Pouch in the Male of *Trichosurus vulpecula*, 688
Bollman, J. H., A Pilot-Channel Regulator for the K-I Carrier System, 287
Bolton, Ethel (Harrison, Prof. J. W. Heslop, Blackburn, Dr. Kathleen B., and), Vitamin C and Chromosome Number in Rosa, 574
Bonacina, L. C. W., Landscape Impression and the External Basis of Natural Beauty, 624
Bor, Dr. N. L., Relict Vegetation of the Shillong Plateau, 213
Boring, Prof. E. G., Illusions about the Size of the Moon, 629
von Born, Ignaz, Bicentenary of the birth of, 763
Born, Prof. Max, *obituary* of Dr. Arnold Berliner, 284
  Thermal Vibrations and Scattering of X-Rays, 353
Born, Prof. M. (Blackman, Dr. M., and), Raman's Theory of of Crystals, 55
Born, Prof. M., and Lonsdale, Dr. K., Temperature Variatio Scattering of X-Rays by Crystals, 490
Borucki, Dr. J., Life of Benedict-Dybowski, 149
Boswell, Prof. P. G. H., Mineral Resources and the Atlantic Ch
  World Mineral Resources, a Suggested Survey, 565
  Geology in China, 649
Boswell, Prof. P. G. H., and others, The Public Schools in Great B
Botanical Institute, The Leningrad, 487
Bourne, C. L. C., appointed government analyst, British Guiana,
Bourne, Dr. Geoffrey, Return to Reason ! an Essay in Political *review* by Dr. Joseph Geoghegan, 472
Bourne, Geoffrey (edited by), Cytology and Cell Physiology, *revie* I. Manton, 362
Bouton, G. M., Lead-Calcium Test Castings, 412
Bowden, Dr. F. P., and Tabor, D., Mechanism of Metallic Friction,
Bowles, Dr. R. F., 'Tack' and Sticky Materials, 160
Bowley, Dr. Agatha H., The Natural Development of the Child, A. W. Wolters, 749
Bowley, Prof. A. L., *obituary* of Sir Alfred William Flux, 228
  A Problem in Econometrics, *review*, 335
Boyland, Dr. E., Cancer Research in Great Britain, 81
Boys, Sir Charles V., A Flight of Pure Imagination, 464
Brabazon of Tara, Lord, Ad Astra (Wilbur Wright Memorial Lect 1942), 15
  Past, Present and Future of Aviation, *review*, 132
  to open the exhibition of Photography's Part in the War arrang Kodak, Ltd., 519
Bradley, Dr. A. J., Determination of Equilibrium Diagrams by Methods, 466
Bradley, Dr. William, joins the scientific staff of British Drug House 459
Brady, George S., Materials Handbook, an Encyclopedia for Purch Agents, Engineers, Executives and Foremen, fourth edition, by Dr. E. H. Tripp, 195
Bragg, Sir Lawrence, Physicists After the War, 75
  appointed a member of the Advisory Council to the Commit the Privy Council for Scientific and Industrial Research, 372
  Functions of the Research Associations, 373
  Determination of Equilibrium Diagrams by X-Ray Methods, 465
  Post-War Education and Training of Physicists, 568
  Index of X-Ray Diffraction Data, 738
Brainerd, Arthur A., and Denning, Matt, Color for Efficiency, 19
Brandenburg, Prof. Kurt, *death* of, 262
Bridgman, P. W., High-Pressure Measurements, 183
Briggs, Dr. William, and Bryan, Prof. G. H., The Tutorial Algebra, revis and rewritten by Dr. George Walker, Vol. 2 : Advanced Cour fifth edition, *review* by F. G. W. Brown, 39, 124
Brightman, R., Man's Relation to the Living World, *review*, 219
  Factory Inspectors and their Work, *review*, 390
  Administrative Evolution : Service or Tyranny ?, *review*, 501
Bristol, The Bishop of, Growth and Activities of the Industrial Chris Fellowship, 399
Bristow, J. R. (Heaton, J. L.), Whittingham, G., and Hughes, Dr. T. Frictional Properties of Bearing Metals, 520
British Association, appointment of a Committee to collaborate with th Allied Technical Advisory Committee on Scientific Problems o Post-war Reconstruction of Agriculture in Europe, 346
  appointment of a Committee on the Applications of Science to Rura Planning, 346
  Report of the Committee on University Education after the War, 716 718
British Association (Division for the Social and International Relations o Science), Conference on Mineral Resources and the Atlantic Charte (Desch, Dr. C. H.), 171, 201
  Conference on Mineral Resources and the Atlantic Charter :—
    Opening Address by Sir Thomas Holland, 364
    Dr. L. Dudley Stamp on The Exploitation of Minerals in relation to National and World Planning, 395
    Dr. C. H. Desch on New Metals and New Methods, 419
    Prof. C. B. Fawcett on Key Metals and the Location of Industry, 451
    Dr. E. F. Armstrong on Minerals, Old and New, from the Sea, 453
    Dr. W. H. Hatfield on Economy in the Use of Ferro-Alloys, 509
    Dr. David Williams on Mineral Resources of the U.S.S.R., 539
    Prof. P. G. H. Boswell on World Mineral Resources, a Suggested Survey, 565
    Sir Harold Hartley on Recovery of Metals from Scrap, 594
British Council, Sir Henry Dale appointed chairman of the Science Committee, 20
  Mission of Cultural and Scientific Co-operation to China, 369, 426
  Map of Europe and Middle East, 543
British Council, the Royal Asiatic Society, the East India Association, and the India Society, Meeting to celebrate the centenary of the birth of Akbar, the Great Mughal, 600
British Drug Houses, Ltd., Dr. William Bradley joins the scientific staff of, 459
British Empire Cancer Campaign, eighteenth annual report of, 81
British Museum, Archbishop Lord Lang of Lambeth and Sir Charle Sherrington elected trustees, 20
  (Natural History), to re-open on August 1, 150
British Social Hygiene Council, Presidential Address by Sir Walter Langdo Brown, 527
  Conference on Social Biology in Education, 555
British Society for International Bibliography, *Proceedings*, Parts I and 2, 6
Britton, Prof. Hubert T. S., Hydrogen Ions, their Determination a Importance in Pure and Industrial Chemistry, third edition, *revi* by Prof. H. L. Riley, 534
Brodetsky, Prof. S., Newton, Scientist and Man, 698
Brodetsky, Prof. S., and others, The Public Schools in Great Britain, 35
Brody, S. B., Structure of Lead Chromate, 740

Brooks, Dr. C. E. P., Radiation from the Sun, 226
  Weather Study, *review*, 645
  Weather Study in the United States, *review*, 728
Brown, C. A. Cameron, and Golding, E. W., Simplified Electrically Heated Hotbeds, 659
Brown, C. C. B., appointed veterinary officer, Tanganyika, 602
Brown, Ernest, War-time Lessons for Peace-time Health, 518
Brown, F. G. W., Higher Algebra, *review*, 39, 124
  Elementary Mathematics (Prof. Hyman Levy), *review*, 507
  Modern Trigonometry (M. J. G. Hearley), *review*, 507
Brown, Dr. G. Burniston, Dimensions, 89
  Validity of the Clausius-Mosotti Formula, 661
Brown, J. N. R., appointed senior agricultural officer, Tanganyika, 602
Brown, P. H., appointed lecturer in horticulture in the Agricultural Department of the University of Leeds, 119
Brown, Dr. William, War and the Psychological Conditions of Peace, *review*, 590
Browne, Geoffrey (Russell, Sir E. J., Kay, Dr. H. D., Ogg, Dr. W. G., Barker, B. T. P., Messer, Malcolm), Garner, F. H., McMillan, J. A., Wilks, T. Nellist, Holmes, Dr. E., Orrell, W. R., and other Experts, Farming Handbook, *review*, 618
Brück, Dr. H., Structure and Rotation of Galaxies, 170
Brundrett, F., Post-War Education and Training of Physicists, 568
Brunt, Prof. David, Weather Study, *review* by Dr. C. E. P. Brooks, 645
Bryan, Prof. G. H. (Briggs, Dr. William and), The Tutorial Algebra, revised and rewritten by Dr. George Walker, Vol. 2 : Advanced Course, fifth edition, *review* by F. G. W. Brown, 39, 124
Bryan, Dr. W. A., *death* of, 262
Bryant, Prof. Ernest C., *death* of, 570
Buck, J. B., and Melland, A. M., Isolation and Collection of Salivary Gland Chromosomes, 352
Buckley, Dr. H., Some Historical Aspects of Newton's Work, 731
Buckley, Dr. Oliver E., Future of Transoceanic Telephony (thirty-third Kelvin Lecture of the Institution of Electrical Engineers), 60
Bullard, Dr. E. C., The Figure of the Earth, 340
Bullough, Dr. W. S., Starlings and Foot-and-Mouth Disease, 739
de Burgh, Prof. W. G., Bradley's Dialectic, *review*, 671
Burke, Frederick, An Inland Record of *Triglochin maritimum* L., 405
  Insect Fauna of a Brine-pit, 610

  resolution referring to the appointment of scientific advisers to the Ministry of Production, 316
Scientific Societies, South-Eastern Union of: Annual Congress (Captain T. Dannreuther), 241
  Dr. J. Ramsbottom elected president for 1942–43, 241
Scientific Workers, Association of: Conference to discuss a Central Scientific and Technical Board, 265, 383
  Conference on Science for Victory, 429
  Exhibition of Photography in Science and Industry, 519
  Conference on Scientists of the United Nations and the War Effort, 602
  (Cambridge University Branch), discussion on Cambridge Scientific Workers and the War, 186
  (North-West Area Committee), conference on Science and Total War, 427
  (University of Manchester Branch), Series of lectures by scientific men engaged on research, 487
  (Society for Cultural Relations with the U.S.S.R., in conjunction with the), Exhibition of Soviet Scientific Films, 342
Scientific Workers, Australian Association of, conferences on the use being made of scientific men in Australia, 494
Scientific and Industrial Research, Australia (Council for), fifteenth annual report of the, 325
Scientific and Industrial Research, Committee of the Privy Council for, Sir Lawrence Bragg, Prof. J. E. Lennard-Jones, Dr. A. McCance and Sir Raymond Street appointed members of the Advisory Council, 372
  Dr. G. M. B. Dobson and S. K. Thornley to retire from the Advisory Council, 372
Scientists (Professional), Joint Council of, 657
Scott, Sir Harold, retiring from the directorship of the Bureau of Hygiene and Tropical Medicine, 232, 263
  work of, 263
  A History of Tropical Medicine, second impression, *review*, 507
Scott, Dr. Murray, Mineral and Vitamin Requirements and the War-time Dietary, 125
Scottish Geographical Society (Royal), Sir D'Arcy W. Thompson elected president, 372
Secrett, F. A., appointed honorary adviser on vegetable production to the Ministry of Agriculture and Fisheries, 288
Segal, Dr. Louis, edited by, New Complete Russian-English Dictionary (New Orthography), *review*, 278
Selby, Prof. A. L., *death* of, 229; *obituary* by Prof. R. T. Dunbar, 285
Selwyn, E. W. H., The Eye in Industry, 80
Seymour, H., Infra-Red Baking of Industrial Finishes, 371
Shakespear, Dr. G. A., *obituary* of Prof. K. N. Moss, 542
  obituary of Sir Charles Hyde, 684
Sharman, Dr. B. C., Onset of Reproductive Phase in Grasses and Cereals, 208
  Developmental Study of the Maize Shoot, 435
Sharp, Abraham, Bicentenary of, 52
Sharp, Dr. J. G., Dried Foods, 223
Sharpe, Sir Montagu, *death* of, 262
Shaw, Miss M., Documentation in an Industrial Laboratory, 601
Shennan, Alderman A. E., Post-War Reconstruction of Liverpool, 297
Sheppard, T., elected an honorary life member of the Yorkshire Federation of Museums and Art Galleries, 119
Sherborn, Dr. C. D., *obituary* by J. R. Norman, 146
Sherrington, Sir Charles, elected a trustee of the British Museum, 20
  Goethe on Nature and on Science, *review* by Prof. E. N. da C. Andrade, 275
Shetzline, R. A., Man-Made Radio Interference, 265
Shidle, Norman G., and Bissell, Thomas A., Motor Vehicles and their Engines, fifth edition, *review*, 74
Shoemaker, Clarence R., American Freshwater Amphipoda, 26
Shokuff, Dr. R. I., Use of Desiccated Chick Embryo in Tissue Culture Technique, 461
Short, Dr. W. F., and others, Notatin, an Anti-bacterial Glucose-aerodehydrogenase from *Penicillium notatum* Westling, 634
Shove, Rosamund F., Buddleias on a Bombed Site, 463
Shull, J. Marion, Horticultural Work on the Amaryllidaceæ, 232
Silk, B. J., appointed agricultural officer, Gold Coast, 346
Silver, Dr. R. S., Tensile Strength of Water and Liquid Structure Theory, 605
Silvester, N. L., Mating Call-note of Moths, 463
Sinclair, Dr. H. M., Mineral and Vitamin Requirements and the War-time Dietary, 125
Singer, Prof. Charles, A Great Country Doctor, 286
Singer, J. H., Analysis of Foods and Drugs, *review*, 674
Singer, Rolf, Type Species of Agaricaceous Genera, 609
Singh, Laksman (Mukerji, Prof. S. K., and), Raman Spectrum of 1, 3, 5-Triphenyl Benzene, 347
Singh, Nand Lal (Asundi, Prof. R. K., and), Selective Excitation of Spectra by the High-Frequency Discharge, 123
Singh, R. S., Propagation of the Apple in Kumaun, 231
Sinott, E. W., Growth and Development, 421
Sjögren, Bertil, Sulphanilamides and Experimental Tuberculosis, 431
Skene, A. A., Earthed-Plate Amplifier for the Frequency-Modulation Transmitter, 438
Skene, Prof. Macgregor, reference to the review entitled 'A Fateful Legacy', 150
Skimm, G. W., Artificial Culture of Prunus Hybrids, 435
Skinner, Prof. John Harrison, *death* of, 86
Skrimshire, G. E. H., and others, Notatin, an Anti-bacterial Glucose-aerodehydrogenase from *Penicillium notatum* Westling, 634
Sloane, Prof. Alvin, Engineering Kinematics, *review*, 73
Slonczewski, T., Automatic Production of Oscillator Scales, 438
Smalley, Lieut. Alan G., Simplification of Musical Notation, 211
Smith, B., Electricity in a Beet-Sugar Factory, 344
Smith, F. E., appointed chief engineer and superintendent of Armament Design, 632
Smith, F. F., and Weiss, F., Relationship of Insects to the Spread of Azalea Flower Spot, 294
Smith, Prof. J. G., Mineral Resources and the Atlantic Charter, 203
Smith, James H. C. (Luck, James Murray, and), (edited by), Annual Review of Biochemistry, Vol. 11, *review* by Dr. E. F. Armstrong, 589
Smith, J. R. E., and Hinshelwood, C. N., Free Radical Chain Reactions, 295
Smith, K. S., The Airgraph Service, 601
Smith, Dr. May, The Human Factor in Production, 142
  A Study of Accidents, 396
Smith, R. R. (Norrish, Prof. R. G. W., and), Catalysed Polymerization of Methyl Methacrylate in the Liquid Phase, 336
Smith, Dr. Stuart G., Response to Colour in Birds, 376
Smith, W., The Distribution of Population and the Location of Industry on Merseyside, 437
Smith-Rose, Dr. R. L., Velocity of Radio-Frequency Waves, 477
  Radio Research, 493
Smuts, General J. C., awarded the Albert Medal of the Royal Society of Arts for 1942, 51
  Plans for a Better World, 161
  Address to the Houses of Parliament, 517
Snell, George D., edited by, Biology of the Laboratory Mouse, *review* by Dr. Hans Grüneberg, 101
Social Research (Economic and), National Institute of, issue of Occasional Papers, 487
Society for Cultural Relations with the U.S.S.R., in conjunction with the Association of Scientific Workers, Exhibition of Soviet Scientific Films, 342
Soddy, Dr. F., and others, The Public Schools in Great Britain, 351

Soutar, M. S., Wilkins, Dr. E. H., and Florence, Dr. P. Sargant, Nutrition and Size of Family, Report on a New Housing Estate, 1939 (Prepared for the Birmingham Social Survey Committee), *review*, 475
South-Eastern Union of Scientific Societies : Annual Congress (Captain T. Dannreuther), 241
  Dr. J. Ramsbottom elected president for 1942–43, 241
Southwell, Prof. R. V., appointed Rector of the Imperial College of Science and Technology, 316
  Stress Distributions in Solids of Revolution, 353
Soviet (Anglo-) Scientific Collaboration Committee, 285

Zuckermann, Dr. Conrado, Classification and Nomenclature of Cancer, 573

SUBJECT INDEX

ABBOTT Farm (The Effect of the) on Eastern Chronology (Dr. Dorothy Cross), 155
Abnormality of Flame Gases (Prof. W. T. David), 320
Abortion (Non-bacterial) in Equines (V. R. Rajagopalan), 231
"Absolute Acceleration", On (Prof. E. A. Milne), 489
Absolute Magnitude, Cyanogen Criterion of (Dorrit Hoffleit), 436
Absorption from Subcutaneously Implanted Tablets of Hexœstrol, Retarding Effect of Ghost Formation on (Dr. S. J. Folley), 735
Absorption Spectra of 3–4 Benzpyrene (Prof. F. Weigert), 56
Absorption and Emission of Radiation in the Atmosphere, 144
Absorption and Scattering of Light in Diamonds (P. G. N. Nayar), 741
A.C. and D.C. Peak-Factor Meter (E. H. W. Banner), 401
Acari, Earthquake on August 24, 288
Acceleration", On "Absolute (Prof. E. A. Milne), 489
Accident, Discoveries by (Prof. Sidney Russ), 735 ; (Prof. H. R. Robinson), 735
Accidents ; A Study of (Dr. May Smith), 396
  The Personal Factor in (Industrial Health Research Board, Emergency Report No. 3), 396
Acid Derivatives (Fatty) in Living Tissues; The Mode of Occurrence of (J. A. Lovern), 294
Acids (Long-chain) containing a Quaternary Carbon Atom (A. J. Birch and Sir R. Robinson), 553
Acoustical Factors in Planning Buildings, *review* by N. Fleming, 193
Acoustics : (Dr. Alexander Wood), *review* by Dr. W. H. George, 248
  (Practical) and Planning against Noise (Hope Bagenal), *review* by N. Fleming, 193
  Text-Books of, *review* by Dr. W. H. George, 248
Action of Ciliated Epithelium of the Frog's Mouth, Demonstration of (G. B. West), 580
Ad Astra (Lord Brabazon of Tara) (Wilbur Wright Memorial Lecture for 1942 of the Royal Aeronautical Society), 15
Adenine Nucleotides (Role of) and Growth Factors in Increased Proliferation following Damage to Cells (Prof. John R. Loofbourow), 349
Administrative Evolution, Service or Tyranny ?, *review* by R. Brightman, 501
Admiralty : Appointments, 687
  Manual of Tides (Dr. A. T. Doodson and Comdr. H. D. Warburg), *review* by Dr. G. R. Goldsbrough, 615
Adolescent Criminal, The (Dr. W. Norwood East, in collaboration with Dr. Percy Stocks and H. T. P. Young), *review* by Prof. Cyril Burt, 361
Adrenaline, 'Heavy' (G. R. Clemo and G. A. Swan), 553
Advances in Medicine, *review*, 309
Aeolotropic Plates, Stress Systems in (A. E. Green), 238
Africa : Anglo-American Collaboration in, 745
  Commission of Forestry Research in (E. N. Corbyn), 379
  Native Medical Practice in, *review*, 36
  (East), Cotton Research in, 117
  (North), The Sky in, 764
  (The Atlantic Charter and) from an American Standpoint (Committee on Africa, the War, and Peace Aims), 745
African Medicine (Native), with Special Reference to its Practice in the Mano Tribe of Liberia (Dr. George Way Harley), *review*, 36
Agar, Constitution of (W. G. M. Jones and S. Peat), 27
Agaricaceous Genera, Type Species of (Rolf Singer), 609
Aggregate (Formation of a Double Crystal) and the Structure of the Intermediate Temperature Modification of $Ni(NO_3)_2.6NH_3$ (S. H. Yü), 347
Agricultural Research Institutes and the Future (Dr. B. A. Keen), 282 ; (Prof. G. W. Robinson), 551
Agricultural Systems, Efficiency and Output in (Prof. A. W. Ashby), 723
Agriculture : Engineering in (Sir John Thornycroft), 542
  The Impact of Science on (Sir John Russell), 311
  in Europe (Post-war Reconstruction of), appointment of a British Association Committee to collaborate with the Allied Technical Advisory Committee on Scientific Problems connected with the, 346
  in Northern Ireland (J. F. Gordon), 734
  To-day and To-morrow (Royal Society of Arts series of lectures), 543
  and the War Stimulus (C. S. Orwin), 637
Air Power and Civilization (M. J. Bernard Davy), *review* by Lord Brabazon of Tara, 132
Aircraft, Michelia Timbers for, 630
Airgraph Service, The (K. S. Smith), 601
Albania, Earthquake in, 288
Albert Medal of the Royal Society of Arts for 1942 awarded to General J. C. Smuts, 51
Alcohol ? What Price (Dr. Robert S. Carroll), *review*, 675
Alcoholism : Psychiatry and (Dr. Merrill Moore), 400
  and Crime (Dr. Ralph S. Banay), 428
Algebra, Higher, *review* by F. G. W. Brown, 39, 124
  The Tutorial (Dr. William Briggs and Prof. G. H. Bryan), revised and rewritten by Dr. George Walker, Vol. 2 : Advanced Course, fifth edition, *review* by F. G. W. Brown), 39, 124
Alkyl Radicals, Counting Free (M. H. Feldman, J. E. Ricci and M. Burton), 740
Allergy, Strangest of all Maladies (Dr. Warren T. Vaughan), *review*, 675
Allies (European), Reconstruction Research conducted in Britain by the (Ethel J. Lindgren), 457
Alloy Cu_3Au, Order in the (L. H. Germer, F. E. Haworth and J. J. Lander), 238
Almora, Earthquake on October 10, 488
Alternating Current (Static Conversion of Direct Current to) with Grid-Controlled Mercury-Arc Mutators (R. Feinberg), 664
Alternating Voltages, Differential Electronic Stabilizer for (Arvon Glynne), 740
Alternator Windings, Travelling Waves in High-Voltage (E. Friedländer), 695
Aluminium Oxide Coatings, Thickness of, 428
Amaryllidaceæ, Horticultural Work on the, 232
Amber Spiders (A. Petrunkevitch), 183
Amenities and Welfare Conditions in the Three Women's Services, Report of the Committee on, 415
America : Private Schools in (Willard Connely), 434
  (Central), Earthquakes on August 6 and August 8, 518
  (Central and South), List of Institutions, Societies and Research Workers in the Pure and Applied Plant Sciences in, (*Chronica Botanica* Co.), 90
  (Central) and Mexico, Archæological Work of the Carnegie Institution in (Dr. Sylvanus G. Morley), 155
  (Latin), Potentialities of the Forests of (Prof. S. J. Record), 89
  (North), Ethnographic Bibliography of (George Peter Murdock), *review* by Mrs. K. Rishbeth, 619
  (South), Early Astronomy in (Roscoe F. Sanford), 174
  (South), Earthquakes on May 14, 118
  (South), Yellow Fever in (Dr. Wilbur A. Sawyer), 176
American : Archæology, Recent Advances in (American Philosophical Society symposium on), 155
  Flour Beetle *Tribolium confusum* Duval, Vitamin Requirement of the (H. Rosenthal and T. Reichstein), 546
  Freshwater Amphipoda (Clarence R. Shoemaker), 26
  Health in Early War Months, 231
  Museum of Natural History, Henry Fairfield Osborn and the (Prof. W. K. Gregory), 513
  Newspaper Reporting of Science News (Hillier Krieghbaum), 174
  Standpoint, The Atlantic Charter and Africa from an (Committee on Africa, the War, and Peace Aims), 745
  (Anglo-) Collaboration in Africa, 745
  (Anglo-) Relations in Reconstruction, 613
  (Inter-) Friendship through the Schools (U.S. Office of Education, Bulletin No. 10, 1941), 54
  (North) Flora, Discovery of the, 89
  (South) Freshwater Fishes, Studies of (George G. Myers), 639
Amines (Pressor), Antipressor and Depressor Effects of Oxidation Products of (Dr. Kurt A. Oster), 289
Amino Acid Analysis and the Structure of Proteins (Prof. A. C. Chibnall), 127
p-Aminobenzoic Acid, Effect of Sulphanilamides on the Growth of Micro-organisms in Presence and Absence of (Sten Wiedling), 290
Amphipoda, American Freshwater (Clarence R. Shoemaker), 26
Amplifier (Earthed-Plate) for the Frequency-Modulation Transmitter (A. A. Skene), 438
Amplifiers, Feedback (C. A. A. Wass), 381
Analysis : of Electrical Contact Effects, 743
  of Economic Time Series, The (Harold T. Davis), *review* by Dr. A. L. Bowley, 335
  of Foods and Drugs, Aids to the (Dr. J. R. Nicholls), sixth edition, *review* by J. H. Singer, 674
  Volumetric (Prof. I. M. Kolthoff and V. A. Stenger), second revised edition, Vol. I : Theoretical Fundamentals, *review*, 504
  (Amino Acid) and the Structure of Proteins (Prof. A. C. Chibnall), 127
  (Photographic) of Motion (E. R. Davies), 765
  and Testing of Coal in relation to its Properties and Utilization (Melchett Lecture by Dr. Arno Carl Fieldner), 372, 667 ; (H. J. Hodsman), 667
Anasazi History, Reconstruction of (Prof. Harold S. Colton), 155
Anatolia, Earthquake on December 3, 687
Anatomy of Freedom, The, *review* by Prof. A. D. Ritchie, 100
Andean Field, Archæology of the (Wendell Cl. Bennett), 157
Anemotaxis : in Drosophila (Dr. H. Kalmus), 405
  in Soft-skinned Animals (Dr. H. Kalmus), 524
Anglo-American : Collaboration in Africa, 745
  Relations in Reconstruction, 613
Aniline, Diethyl Sulphide, and two Binary Liquid Mixtures, Raman Frequencies of, (Dr. C. S. Venkateswaran and N. S. Pandya), 741
Animal : Fibres, Scaliness of (N. H. Chamberlain and Prof. J. B. Speakman), 546
  Health Corporation, formation of an, 501
  Parasites, Immunity against (Prof. James T. Culbertson), *review* by Lieut.-Colonel F. Murgatroyd, 360
  Psychology, The Discrimination Method in (Dr. H. Honigmann), 296
  (Test) for Tubercular Infection, The Golden Hamster as a (Dr. J. Ungar), 432
Animals : Spontaneous and Experimental Leukæmia in (Engelbreth-Holm, Dr. Julius), *review* by Prof. G. R. Cameron, 133
  Tea Leaves as a Maintenance Food for (W. King Wilson), 199
  (Soft-skinned), Anemotaxis in (Dr. H. Kalmus), 524
Animals and Plants, Rapid Determination of Fat in (A. G. Lowndes), 291
Animals (Plants and), The Causes of the Intertidal Zonation of (Linnean Society discussion on), 158
Annealing of Glass Bottles and Containers, Application of Electricity to the (E. S. Morris), 400
Annelid Worms (Marine) in the United States National Museum, The Identity of some (Olga Hartman), 609
Annual Review : of Biochemistry (James Murray Luck, editor ; James H. C. Smith, associate editor), Vol. 11, *review* by Dr. E. F. Armstrong, 589
  of Physiology (James Murray Luck, editor ; Victor E. Hall, associate editor), Vol. 4, *review* by Prof. C. Lovatt Evans, 276
Anthropological Surveys, War-time Uses of, 385
Anthropology in Switzerland, 150
Antigua (South-west of), Earthquakes on August 6 and August 8, 518
Antipressor and Depressor Effects of Oxidation Products of Pressor Amines (Dr. Kurt A. Oster), 289
Aphides, Bean and Dock, 294
Aphids (G. Fox-Wilson), 90
Aphis (*Doralis*) *rumicis* L. and comparison with *Aphis* (*Doralis*) *fabae* Scop. (Margaret E. Jones), 294
Apocalypse of St. John, New Light on the, *review*, 363

Apparatus (Historic Machines and), Preservation of (E. Lancaster Burne and H. W. Dickinson), 181
Apple in Kumaun, Propagation of the (R. S. Singh), 231
Apples, Volatile Products from (L. P. Walls), 608
Application of the Study of Vibration to Engineering Design, *review*, 392
Appotettix eurycephalus, Translocations in (R. K. Nabours, F. M. Stebbins and W. R. B. Robertson), 26
Apricots, 'Die-back' Disease of (H. Denham and H. Wormald), 630
Archæological Research (Recent) in Transcaucasia (Prof. Ellis H. Minns), 28
Archæological Work of the Carnegie Institution in Central America and Mexico (Dr. Sylvanus G. Morley), 155
Archæology : of the Andean Field (Wendell Cl. Bennett), 157
  (American), Recent Advances in (American Philosophical Society symposium on), 155
  Swedish, 573
  (North Syrian) and Old Testament Sources (M. C. Burkitt), 327
Arctic Ocean, Depths of the, 734
Areas (Mean) and Heliographic Latitudes of Sunspots during 1938 (Dr. H. Spencer Jones), 353
Argentine : Prevention of Heart Disease in (Dr. Hugh J. D'Amato), 206
  Prophylaxis of Malaria in (Dr. Hugo J. D'Amato), 118
  Trachoma in the, 176
  Tuberculosis Control in (Dr. Hugo J. D'Amato), 545
Arginase, Formation of Urea in the Mammalian Body without Participation of (Dr. S. J. Bach and S. Williamson), 575
Army (United States), Health of the, 631
Art in War-time, Care of Works of (F. Ian G. Rawlins), 112
Artificial Culture : of Datura embryos (J. van Overbeek, M. E. Conklin, and A. F. Blakeslee), 435
  of Prunus Hybrids (G. W. Skimm), 435
Ascorbic Acid and Dehydro-Ascorbic Acid, Use of Formaldehyde in the Estimation of (J. W. H. Lugg), 577
Ashes (Out of the), a Survey of the Unhappy Lands and a Design for International Harmony (Thorborn Muirhead), *review* by F. S. Marvin, 6
Aspects (Sociological) of Production Committees, 1
Assam : (Forest Administration in the Province of) for the year 1940–41, Report of (C. Mackarness), 440
  Forestry in, 440
Assay (Physiological) of Pyrethrum Extracts, A Method of (Dr. Otto Lowenstein), 760
Astro-Navigation, The Observer's Book on, (Flight-Lieut. Francis Chichester), Part 4, *review*, 8
Astronomer Royal, Report of the, 1941–1942, 212
Astronomy : on Postage Stamps, 229
  (Early) in South America (Roscoe F. Sanford), 174
Astrophysical Observatory : (Mexican National) at Tonanzintla, dedication marked by the issue of postage stamps, 229
  of the Smithsonian Institution, Annals of the (C. G. Abbot, L. B. Aldrich and W. H. Hoover), Vol. 6, 226
Astrophysics, Spectroscopy in, 601
Atlantic Charter : and Africa from an American Standpoint (Committee on Africa, the War, and Peace Aims), 745
  (Mineral Resources and the) (British Association, Division for the Social and International Relations of Science, Conference on), 171, 201
Atlas : (Star) for the Latitude of Egypt (H. E. Hurst, M. R. Madwar and A. H. Samaha), second edition, 764
  (Regional Survey) of the Croydon District (Croydon Natural History and Scientific Society), 766
Atmosphere : The Temperature of the (Dr. T. G. Cowling), 686 ; (Dr. L. Jánossy), 686
  (Radiation in the), Absorption and Emission of, 144
Atomic Nucleus by Spectroscopic Methods, The Study of (Dr. S. Tolansky), 487
Atomic Physics, Introduction to (Dr. S. Tolansky), *review* by Prof. A. M. Tyndall, 308
Atoms : Sixth Report of the International Union of Chemistry Committee on, 515
  Valency Configurations of (Dr. W. H. Mills), 572
Auriculas (Sir Rowland Biffen), 238
Austerity Thinking, *review* by Miss E. I. Black, 417
Australia : Biology and Cultivation of Oysters in (G. Humphreys), 544
  Council for Scientific and Industrial Research, fifteenth annual report of the, 325
  Refrigeration of Fish in, 458
Autoelectronic Emission from Single Crystal Metal Points (M. Benjamin and R. O. Jenkins), 295
Automatic Production of Oscillator Scales (T. Slonczewski), 438
Automobile Research, 243
Autonomy of Life, The Problem of the (Prof. Reginald O. Kapp), 123 ; (Prof. F. G. Donnan), 123
Auxin and Leaf-Protein (S. G. Wildman and S. A. Gordon), 608
Aviation, Past, Present and Future of, *review* by Lord Brabazon of Tara, 132
Azalea Flower Spot, Relationship of Insects to the Spread of (F. F. Smith and F. Weiss), 294
Azores, Earthquake swarm in the, 488
Aztec Pantheon, Attributes and Nature of the (Dr. Hans Dietschy), 150
Aztecs, The, their Cultural and Historical Position in Middle American Archæology (Dr. George C. Vaillant), 155

B_1 (Biotin), Riboflavin, Nicotinic Acid, B_6 and Pantothenic Acid as Growth Factors for Insects (Dr. G. Fraenkel and M. Blewett), 177
B_6 (Biotin, B_1, Riboflavin, Nicotinic Acid) and Pantothenic Acid as Growth Factors for Insects (Dr. G. Fraenkel and M. Blewett), 177
Back to Better Grass (I. G. Lewis), *review*, 392
Bacon (Francis), Vitamin C in the Days of (Prof. E. L. Kennaway), 491
Bacot Memorial Lecture of the Lister Institute of Preventive Medicine, to be delivered by Prof. P. A. Buxton, 488
Bacteria : (Intestinal), Synthesis of Vitamins by (P. R. Burkholder and I. McVeigh), 553
  (Fungi and), High-Concentration Hydrogen Cyanide Fumigation of (Dr. N. Polunin), 682
Bacterial Canker of the Peach (H. Wormald), 295
Bacterial Fermentation, Potassium in (Dr. J. Leibowitz and N. Kupermintz), 233
Bacterial Reduction of Tetrathionate (M. R. Pollock, R. Knox and P. G. H. Gell), 94
Bagasse for the Manufacture of Paper and Board (M. P. Bhargava and A. N. Nayer), 88
Bakerian Lecture on Amino Acid Analysis and the Structure of Proteins (Prof. A. C. Chibnall), 127
Baking (Infra-red) of Industrial Finishes (H. Seymour), 371
Balkans, Earthquake on August 27, 238, 345
Baroque Literature (German), Magic and Natural Science in (Frederick Herbert Wagman), *review*, 619
Barrier Reef (Great) Bores (H. C. Richards and Dorothy Hill), 739
Basis of Life, The Physical, *review* by Dr. I. Manton, 362
Basle (north-west of), Earthquake on July 18, 545
Battery Separators, Indian Woods for, 630
Bean and Dock Aphides, 294
Bearing Metals, Frictional Properties of (J. L. Heaton, J. R. Bristow, G. Whittingham and Dr. T. P. Hughes), 520
Beauty (Natural), Landscape Impression and the External Basis of (L. C. W. Bonacina), 624
Bed-bug, Biology and Control of the, 427
Bed-bug Infestation, 1935–1940, Report of the Committee on (Medical Research Council), 427
Bee, The Honey (Dr. C. G. Butler), 759
Beet (Spinach), A Red Colouring Matter from the Green Leaves of (Ralph J. B. Marsden), 580 ; (H. G. Baker), 689
Beet Leafhopper (W. C. Cook), 175
Beet-Sugar Factory, Electricity in a (B. Smith), 344
Beetle (American Flour), *Tribolium confusum* Duval, Vitamin Requirement of the (H. Rosenthal and T. Reichstein), 546
Beetles (Four Common Carpet), Studies on the Biology of (Grace H. Griswold and Margaret Greenwald), 182
Behaviour: of Sulphur in Rubber (G. G. Winspear), 31
  (Schooling) of Mackerel (Arthur Schlaifer), 663
Behring Prize (Emil von) of the University of Marburg awarded to Prof. Paul Uhlenhuth, 545
Beit Memorial Fellowships for Medical Research, 119
  Dr. A. N. Drury appointed to the Advisory Board, 119
  elections to, 119
Benzene (1, 3, 5-Triphenyl), Raman Spectrum of (Prof. S. K. Mukerji and Laksman Singh), 347
Benzpyrene (Transformation of) in the Living Skin of Mice into a Compound Soluble in Dilute Alkali (J. C. Mottram and Prof. F. Weigert), 635
3-4 Benzpyrene : Absorption Spectra of (Prof. F. Weigert), 56
  A Water-soluble Carcinogen Derived from (Dr. C. B. Allsopp), 548
Berkeley, California, Earthquake registered on November 10, 602
Bermudan Nemerteans, *Gorgonorhynchus bermudensis* n.sp., Notes on (Dr. J. F. G. Wheeler), 583
Berneroberland, Earthquake between Simmental and Kandertal, on February 17, 175
Beveridge Security Plan, 753
Bibliographia Primatologica, Part 1 : Anatomy, Embryology and Quantitative Morphology ; Physiology, Pharmacology and Psychobiology ; Primate Phylogeny and Miscellanea (Theodore C. Ruch), *review*, 74
Bibliography : Physics, 90
  of Seismology (Ernest A. Hodgson), Vol. 13, No. 11, January to June, 1942, 459
  (Ethnographic) of North America (George Peter Murdock), *review* by Mrs. K. Rishbeth, 619
  (International), British Society for, *Proceedings*, Parts 1 and 2, 601
Binary Star System, An Important (Dr. R. M. Petrie), 545
Biochemistry : Annual Review of (edited by James Murray Luck and James H. C. Smith), Vol. 11, *review* by Dr. E. F. Armstrong, 589
  General and Particular, *review* by Dr. E. F. Armstrong, 589
  and Genetics (E. L. Tatum and G. W. Beadle), 552
Biography of the Earth (Prof. George Gamow), *review* by Prof. A. Holmes, 391
Biological Discoveries (Some) of Practical Importance (Dr. C. H. Waddington), 257
Biological Movement, Nomenclature of (Cyril Bibby), 405
Biological Sciences, Planning in the (Dr. D. McClean), 384
Biology : Educational (Hugh Ramage), 542
  An Experimental Human (Cyril Bibby), *review* by Dr. D. L. Gunn, 562
  General and Social (Sir James W. Barrett), 124
  Modern, *review* by Dr. D. L. Gunn, 562
  Physics in, *review* by Dr. Harold Jeffreys, 332
  and Control of the Bed-bug, 427
  of Four Common Carpet Beetles, Studies on the (Grace H. Griswold and Margaret Greenwald), 182
  of the Cuckoo, *review* by Dr. F. H. A. Marshall, 221
  of Man, Fungi and the (Dr. J. Ramsbottom), 242
  of the Larch-Shoot Moth (Bryan P. Beirne), 435
  of the Laboratory Mouse (The Staff of the Roscoe B. Jackson Memorial Laboratory, edited by George D. Snell), *review* by Dr. Hans Grüneberg, 101
  and Cultivation of Oysters in Australia (G. Humphreys), 544
  of the Parasites of the Shisham Defoliators in the Punjab Plantations (R. N. Mathur and C. F. C. Beeson), 552
  of Young Salmon, *S. salar*, Linn. (Prof. J. H. Orton), 21
  of a Carnivorous Snail, 663
  in Brazil, 90
  and Human Welfare (Sir John Orr), 205
  (Social) in Education (British Social Hygiene Council conference on), 555

  (Social) in the Sciences, The Place of (Sir Walter Langdon-Brown), 527
  (Social) for Teachers in Training (Mrs. E. J. Hatfield), 555
Bios Components (Ultra-violet Injured Yeast Cells and of), Proliferation-promoting Activities of Extracts from (Prof. Elton S. Cook and Sister Ann Gertrude Cronin), 93
Biotin, B_1, Riboflavin, Nicotinic Acid, B_6 and Pantothenic Acid as Growth Factors for Insetts (Dr. G. Fraenkel and M. Blewett), 177
Birds : Response to Colour in (Dr. Stuart G. Smith), 376
  (British, A Check-List of (H. F. Witherby), revised edition, *review* by Seton Gordon, 40 ; N. B. Kinnear, 235
  (Nestitng), The War and, 264

Birth-Rate, The Falling, *review*, 646
Black Byzantium, the Kingdom of Nupe in Nigeria (Dr. S. F. Nadel), *review* by Dr. C. K. Meek, 749
Blackcurrants, Vitamin P in (Dr. A. Pollard), 490
Blood Plasma and Blood Serum, Drying, 18
Blood Serum, Drying Blood Plasma and, 18
Blood Vascular System of *Xenopus laevis* (Naomi Millard), 739
Blueprints for a New Science, *review* by J. Drever, 418
Board (Paper and), Bagasse for the Manufacture of (M. P. Bhargava and A. N. Nayer), 88
Bodenunruhe, Earthquake on February 18, 175
Body (Formation of Urea in the Mammalian) without Participation of Arginase (Dr. S. J. Bach and S. Williamson), 575
Body and Self, One and Inseparable (Percy A. Campbell), *review*, 446
'Bog-Butter' from Skye (M. C. Burkitt), 29 ; (Prof. J. Ritchie), 29
Bombed Site, Buddleias on a (Rosamund F. Shove), 463
Bombed Sites, Plant Ecology of (Lady Hartog), 320
Bomber for the R.A.F., New Light Day, 733
Book of Revelation is History (H. S. Bellamy), *review*, 363
Book (Printed), The Typewriter as the Foundation of the (H. Rottenburg), 601
Books : on Historical Medicine and Science, 631
  Recent Scientific and Technical, Supp. ii, July 25 ; Supp. ii, August 29 ; Supp. ii, September 26 ; Supp. ii, October 31 ; Supp. ii, November 28 ; Supp. ii, December 26
  and Periodicals, War-time (B. M. Headicar), 638
Bores, Great Barrier Reef (H. C. Richards and Dorothy Hill), 739
Botany, Readings in the History of, *review* by Prof. W. Stiles, 672
Bournville Village Trust, 230
Bracken (A Chlorosis of) due to Manganese Deficiency (James G. Hunter), 578
Bradley's Dialectic (Dr. Ralph Withington Church), *review* by Prof. W. G. de Burgh, 671
Bragg (first Sir William) Memorial Lecture of the Chemical Society to be delivered by Prof. J. D. Bernal, 488
Brassica Crops, Genetic Classification of (P. T. Thomas and M. B. Crane), 431
Brassica oleracea, Origin of Tetraploid Shoots in (H. W. Howard), 739
Brauner (Mendeléeff-) Tradition in Czech Chemistry (Dr. Gerald Druce), 623
Brazil : Biology in, 90
  Leprosy in (Eunice Weaver), 317
  Public Health in (Dr. João de Barros Barreto), 631
  Yellow Fever in (Dr. Waldemar Antunes), 573
Brazilian Forest Soils, Water Reserves in (Felix Rawitscher), 183
Bread, National Flour and, Second Report, 538
Breeding (On the Feeding and) of *Calanus finmarchicus* (J. E. G. Raymont and Dr. F. Gross), 327
Brine-Pit, Insect Fauna of a (Frederick Burke), 610
Bristol Channel, Marine Fauna of (R. Bassindale), 435
Britain : The Record of Picturesque (Dr. Vaughan Cornish), 63
  Flora of late Lower Old Red Sandstone Age in (W. N. Croft and W. H. Lang), 352
  (Is) a Democracy (Frank Hardie), *review*, 447
  War-time Farming in, *review*, 618
  (Reconstruction Research conducted in) by the European Allies (Ethel J. Lindgren), 457
  Relations with (Committee of the Editors of *Time*, *Life* and *Fortune*), 33

Carbon Monoxide, Energy of Dissociation of (Dr. A. G. Gaydon and Dr. W. G. Penney), 406
Carboniferous Lycopods (J. M. Schopf), 26
Carborundum Ceramic Non-Linear Resistor, Contact Non-Linearity with reference to the Metal Rectifier and the (A. Fairweather), 743
Carcinogen (A Water-soluble) Derived from 3 : 4-Benzpyrene (Dr. C. B. Allsopp), 548
Cardiology, A Short History of (Prof. James B. Herrick), *review* by Sir Thomas Lewis, 561
Carnegie Institution (Archæological Work of the) in Central America and Mexico (Dr. Sylvanus G. Morley), 155
Carpet Beetles (Four Common), Studies on the Biology of (Grace H. Griswold and Margaret Greenwald), 182
Carrier System (K-1), A Pilot-Channel Regulator for the (J. H. Bollman), 287
γ Cassiopeiæ, Changes in the Spectra of (Miss E. M. Peachey), 353
Castings, Lead-Calcium Test (G. M. Bouton), 412
Catalysed Polymerization of Methyl Methacrylate in the Liquid Phase (Prof. R. G. W. Norrish and R. R. Smith), 336
Catalysts for Sodium Chlorate in Weed Destruction (Dr. Ernest A. Dancaster), 737
Cathode Ray Tube and its Applications (G. Parr), second edition, *review*, 74
Cattle Hides, Putrefaction in (Dr. D. Jordan Lloyd), 439
Cave and Lake Bed Cultures of South Central Oregon in the Northern Great Basin (L. S. Cressman), 157
Cell Growth (Effect of Extracts of Heterologous Adult Tissue on) *in vitro* and their Use in Wound Healing (Prof. L. Doljanski, R. S. Hoffman and E. Tenenbaum), 23
Cell Growth-Promoting Principles in Adult Tissue Extract, Partial Purification of (H. Werner and Dr. L. Doljanski), 660
Cell Membrane, Potassium, Fermentation and the (Prof. Edward J. Conway), 461
Cell Physiology, Cytology and (edited by Geoffrey Bourne), *review* by Dr. I. Manton, 362
Cell Respiration, *review* by Dr. F. Dickens, 277
Cellobiose, Synthesis of (W. T. Haskins, R. M. Hann and C. S. Hudson), 553
Cells (Germ) of the Mouse, Cytoplasmic Inclusions in the (Dr. R. A. R. Gresson), 663
Cellulose : An Introduction to the Chemistry of (J. T. Marsh and Dr. F. C. Wood), second edition, *review* by Dr. Julius Grant, 7
  Age, The, *review* by Dr. Julius Grant, 7
  (Starch and) in Herbivora, Microbial Factors in the Digestive Assimilation of (Frank Baker), 479
Census Method (A Relative) for Brown Rats (*Rattus norvegicus*) (Dennis Chitty), 59
Centenary of the Government Laboratory, Department of the Government Chemist (Dr. A. G. Francis), 567
Cereals (Grasses and), Onset of Reproductive Phase in (Dr. B. C. Sharman), 208
Cetacea (Lancashire), Records of (Eric Hardy), 492
Ceylon, Health of, 90
Chadwick Medal and Prize, to be presented to Wilfred Glyndon May, 346
Chadwick Public Lecture : Effects of Clothing and Fuel Shortage on Health (Sir Leonard Hill), 346, 536
  Land Settlement—its Sanitary and Architectural Aspects and After-War Possibilities (Miss Jocelyn F. Adburgham), 571
  Thirtieth annual series of, 346
Chain Reactions, Free Radical (J. R. E. Smith and Prof. C. N. Hinshelwood), 295
Characters (Acquired), Canalization of Development and the Inheritance of (Dr. C. H. Waddington), 563
Chart, A Rheological (L. Bilmes), 432
Charts (Iso-Magnetic) of the Globe (W. M. Witchell), 439; (Prof. Sydney Chapman), 439
Chemical Constitution, Viscosity and (Dr. J. Newton Friend), 432
Chemical Engineering : at Leeds, 53
  Thermodynamics and, *review* by Prof. D. M. Newitt, 37
Chemical Industries (edited by L. Ivanovszky), sixteenth edition, *review*, 507

Chemical Industry Medal for 1942 awarded to Dr. Harrison E. Howe by the American Society of Chemical Industry, 372
Chemistry: The Humanities of, *review* by Dr. E. F. Armstrong, 475
  of Cellulose, An Introduction to the, (J. T. Marsh and Dr. F. C. Wood), second edition, *review* by Dr. Julius Grant, 7
  of Surfaces, The Physics and (Prof. Neil Kensington Adam), third edition, *review* by Prof. Eric K. Rideal, 730
  (Czech), The Mendeléeff-Brauner Tradition in (Dr. Gerald Druce), 623
  (Inorganic), Collateral Readings in, Second Series (edited by L. A. Goldblatt), *review* by Dr. E. F. Armstrong, 475
  (Pure and Industrial), Hydrogen Ions in, *review* by Prof. H. L. Riley, 534
  (Purification and) of Penicillin (Dr. J. R. Catch, Dr. A. H. Cook and Prof. I. M. Heilbron), 633
Chemotherapy and Tuberculosis, 517
Chiasmata (Localized) in *Fritillaria meleagris* (H. N. Barber), 26
Chick Embryo (Use of Desiccated) in Tissue Culture Technique (Dr. R. I. Shujoff), 461
Child, The Natural Development of the (Dr. Agatha H. Bowley), *review* by A. W. Wolters, 749
Child Psychology, *review* by A. W. Wolters, 749
Chile: Earthquake at Santiago and Valparaiso on June 29, 54
  Earthquake south-east of Rancagua on June 29, 207
  Earthquake on July 8, 632
  Public Health in (Dr. Pedro Aguirre Cerda), 118
China: Cultural and Scientific Mission to, 369, 426
  Geology in (Prof. P. G. H. Boswell), 649
China Sea, Earthquake on April 8, 401
Chinese Geology during the past Twenty Years, Progress in (Dr. J. S. Lee), 649
Chironomid, *Spaniotoma minima*, Mating Swarm in a (Dr. N. H. E. Gibson), 268
Chloride Solutions, Distribution of Attack on Iron or Zinc Partly Immersed in (Dr. Ulick R. Evans), 151
Chlorosis: of Bracken due to Manganese Deficiency (James G. Hunter), 578
  in Tomatoes (B. T. Cromwell and J. G. Hunter), 606
Christian Fellowship (Industrial), Growth and Activities of the (The Bishop of Bristol), 399
Chromatophore (Stellate) in the Polychæta (Dr. M. V. Lebour), 209
Chromosome Number in Rosa, Vitamin C and (Prof. J. W. Heslop Harrison, Dr. Kathleen B. Blackburn, and Ethel Bolton), 574; (Dr. Ronald Melville and Dr. Magnus Pyke), 574; (Dr. C. D. Darlington), 404, 574
Chromosomes: Coiling of (G. B. Wilson and I. Hutcheson), 182; (A. H. Sparrow, C. L. Huskins and G. B. Wilson), 182
  The Handling of (Dr. C. D. Darlington and L. F. LaCour), *review* by Dr. Irene Manton, 102
  (Salivary Gland), Isolation and Structure of (J. B. Buck and A. M. Melland), 352
  (Salivary Gland), Structure of (M. Kodani), 352
  (Salivary Gland) in Mosquitoes (Eileen Sutton), 553
Chronology: in the Middle West (Prof. Fay-Cooper Cole), 155
  (Eastern), The Effect of the Abbott Farm on (Dr. Dorothy Cross), 155
Church: as a Social Force, 399, 469
  Looks Forward, The, 399
Ciliary Movement and the Density of Pleurobranchia (A. G. Lowndes), 579
Ciliated Epithelium of the Frog's Mouth, Demonstration of Action of (G. B. West), 580
Circuit Continuity Test, A New (A. F. Burns), 88
Circuits: Thermionic Valve (Dr. Emrys Williams), *review*, 74
  Frequency Stability of Tuned (C. W. Eggleton), 765
Citizenship, Discussions on, *review*, 447
City Growth, Planned, 87
Civil Defence against War Gases, 642; (Prof. J. B. S. Haldane), 769
Civil Service, Recruitment of the, 733
Civil and Municipal Services, Reconstruction in the (G. D. H. Cole), 331
Civilization, Air Power and (M. J. Bernard Davy), *review* by Lord Brabazon of Tara, 132
Classification: (Genetic) of Brassica Crops (P. T. Thomas and M. B. Crane), 431
  and Nomenclature of Cancer (Dr. Conrado Zuckermann), 573
Clausius-Mosotti Formula, Validity of the (Dr. G. Burniston Brown), 661
Clostridium welchii Types *A* and *C*, Artificially Induced Loss of Θ-Toxin Production by (Dr. A. W. Turner, Catharine Eales and A. W. Rodwell), 549
Clothing and Fuel Shortage on Health, Effects of (Sir Leonard Hill), 346, 536
Clusters (Galactic): Structure of (George Alter), 664
  in relation to the Galaxy (George Alter), 740
Coal: (The Analysis and Testing of) in relation to its Properties and Utilization (Melchett Lecture by Dr. Arno Carl Fieldner), 372, 667; (H. J. Hodsman), 667
  Optical Reflections from (C. G. Cannon and Dr. W. H. George), 690
  Utilization, Research on (Sir Evan Williams), 763
Coal-Tar Dyestuffs, Dyeing with (C. M. Whittaker and C. C. Wilcock), fourth edition, *review* by Dr. E. F. Armstrong, 618
Coatings (Aluminium Oxide), Thickness of, 428
Cobalt, Crystal Structure of (O. S. Edwards and H. Lipson), 295; (A. J. C. Wison), 295
Cobalt-Nickel Deposition (C. C. Downie), 187
Cochise-Mogollon-Hohokam Sequence, A Possible (Emil W. Haury), 157
Coiling: of Chromosomes (G. B. Wilson and I. Hutcheson, 182; (A. H. Sparrow, C. L. Huskins and G. B. Wilson), 182
  Tracing Plane Spiral (F. Wolverson Cope), 210
  (Plane Spiral) of Small Fossil Lamellibranchs, Optical Projection as an Aid in Studying (Lieut. A. T. J. Dollar), 57
Coils (Contactor), Voltage Surges caused by (J. R. Taylor and C. E. Randall), 664
Colchicine, Effect of (J. G. Hawkes), 739
Collaboration: in the British Empire, 370
  (Anglo-American) in Africa, 745
Collateral Readings in Inorganic Chemistry, Second Series (edited by L. A. Goldblatt), *review* by Dr. E. F. Armstrong, 475
Collection (Isolation and) of Salivary Gland Chromosomes (J. B. Buck and A. M. Melland), 352
Colonial Development the Progress to Partnership, 161
Colonial Empire, Our Responsibility for Human Quality in the (Sir Francis Fremantle), 555
Colonial Office, Activities and Plans of the (Harold Macmillan), 17
Colonial Policy, 17, 657; (Viscount Cranborne), 686
Colonial Research Committee: 17
  Scope and Purpose of, 51
Colonial Service appointments, 90, 207, 346, 488, 602
Color for Efficiency (Matt. Denning and Arthur A. Brainerd), 19
Colour: in Birds, Response to (Dr. Stuart G. Smith), 376
  of Conductor Insulation Papers (C. T. Wyman), 428
  A Popular Index to, *review* by Dr. Sampson Clay, 70
  of Machines and Workshop Efficiency, 19
  in Schools, The Teaching of (E. G. Savage), 422
  in Telephone Cables, Determining, 428
Colour Chart, Horticultural, Vol. 2 (British Colour Council in collaboration with the Royal Horticultural Society), *review* by Dr. Sampson Clay, 70
Colour Neurohumour in Sharks, Selachine as a (G. H. Parker), 182
Colouring Matter (A Red) from the Green Leaves of Spinach Beet (Ralph J. B. Marsden), 580; (H. G. Baker), 689
Comet: A New (Oterma), 632
  Forbes (Periodic), 1929 ii, 232
  Whipple 1942*a*, Gualberto M. Iannini to compute an orbit, 372
Commission of Forestry Research in Africa (E. N. Corbyn), 379
Communication Progress, Milestones of (H. T. Kohlhaas), 63
Compound Soluble in Dilute Alkali, Transformation of Benzpyrene in the Living Skin of Mice into a (J. C. Mottram and Prof. F. Weigert), 635
Compression-Ignition Engine, The High-Speed (C. B. Dicksee), *review* by Prof. S. J. Davies, 752
Compton Field Station of the Agricultural Research Council, Dr. W. S. Gordon appointed director, 148
Concrete Simply Explained (Victor S. Wigmore), 232
Condition of Freshly Burnt Gases (Dr. A. G. Gaydon), 481, 636; (Prof. W. T. David), 636
Conditioned Reflexes, Lectures on, Vol. 2: Conditioned Reflexes and Psychiatry (Prof. Ivan Petrovitch Pavlov), *review* by Dr. D. Whitteridge, 135
Conductivity of Varnish Films and their Variation with Temperature, Intrinsic Electric Strength and (A. Morris Thomas and Miss M. V. Griffith), 770
Conductor Insulation Papers, Colour of (C. T. Wyman), 428
Conductors, Ice on, 345
Configurations (Valency) of Atoms (Dr. W. H. Mills), 572
Conical Refraction (Sidney Melmore), 382
Conquest of Time (H. G. Wells), *review* by Prof. Herbert Dingle, 444
Constants (Elastic) of Metal Crystals (K. Fuchs and H. W. Peng), 436
Constitution: of Agar (W. G. M. Jones and S. Peat), 27
  (Chemical), Viscosity and (Dr. J. Newton Friend), 432
Consumption (Production,) and Distribution, World Co-operation in, 387
Contact Effects (Electrical), Analysis of, 743
Contact Non-Linearity, with reference to the Metal Rectifier and the Carborundum Ceramic Non-Linear Resistor (A. Fairweather), 743
Contact Resistance (Effects of) on Temperature Rise in Switches (R. W. J. Cockram), 355
Contactor Coils, Voltage Surges caused by (J. R. Taylor and C. E. Randall), 664
Content of Mathematics, The, *review* by Prof. G. H. Hardy, 673
Continuity Test, A New Circuit (A. F. Burns), 88
Control: (Biology and) of the Bed-bug, 427
  (Statistical ('Quality')) of Production (Sir Charles Darwin), 117
Conversion (Static) of Direct Current to Alternating Current with Grid-Controlled Mercury-Arc Mutators (R. Feinberg), 664
Conveyor Belt Dipper, Seed Potato Disinfection by (C. T. N. Wakely and H. C. Mellor), 769
Conway Memorial Lecture on Ethical Ideals in India To-day (Dr. Edward Thompson), 131
Co-operation: to Morale, Relation of, 669
  (World) in Production, Consumption and Distribution, 387
Copley Medal of the Royal Society awarded to Sir Robert Robinson, 571, 665
Copper (Oxidation by) in Alcoholic Medium (Dr. E. M. Mystkowski), 234
Copper Compounds (H. B. Weiser, W. O. Milligan and E. L. Cook), 27
Copper-bearing Protein in Cow's Milk (W. L. Dills and J. M. Nelson), 609
Copyright, International (G. Wren Howard and Stanley Unwin), 658
Cords, Surface Finish and the Quality of Glassware (A. J. Holland, Eric Preston and Prof. W. E. S. Turner), 27
Cork Substitutes, Note on some Experiments on (Dr. N. Narayanamurti, J. N. Pande and D. C. Roy), 230
Coronium Lines, Origin of the (Dr. A. Hunter), 756
Cosmic Radiation (Connexion between the Penetrating Non-ionizing Component of) and Penetrating Showers (Dr. L. Jánossy and Dr. G. D. Rochester), 633
Cosmic-Ray: Radio Guide (H. V. Neher and W. H. Pickering), 244
  Research, Expedition of the Academy of Sciences of the U.S.S.R., 54
Cosmic Rays, Origin of (R. A. Millikan), 244; (H. V. Neher and W. H. Pickering), 244
Cosmogony and Religion, *review* by Sir James Jeans, 671
Cosmology, Deductive, *review* by Dr. G. C. McVittie, 308
Cotton Research in East Africa, 117
Counting Free Alkyl Radicals (M. H. Feldman, J. E. Ricci and M. Burton), 740
Countryside, The English, 441
Couvade, The (L. F. Newman), 734
Cow's Milk, Copper-bearing Protein in (W. L. Dills and J. M. Nelson), 609
Crack Detectors, Magnetic, 344
Cracks: (Detection of) in Engineering Materials, 343
  (Soil), Function of (Dr. A. Sreenivasan), 409
Crannog (The Lake-dwelling or) in Eadarloch, Loch Treig (Prof. James Ritchie), 639
Crater Lake, the Story of its Origin (H. Williams), *review* by Dr. E. B. Bailey, 3
Crime, Alcoholism and (Dr. Ralph S. Banay), 428
Criminal, The Adolescent (Dr. W. Norwood East, in collaboration with Dr. Percy Stocks and H. T. P. Young), *review* by Prof. Cyril Burt, 361
Crisis (Present), The University and the (Prof. A. J. Willard), 97
Criterion (Cyanogen) of Absolute Magnitude (Dorrit Hoffleit), 436
Crop Yields (Cultivation and), Soil Physics, Soil Cultivation, and (Dr. B. A. Keen), 264

Croydon District: Bronze Age Map of the (A. W. G. Lowther), 766
  Bronze Age Remains of the (C. C. Fagg), 766
  Natural Vegetation of the (C., T. Prime), 766
  Regional Survey Atlas of the (Croydon Natural History and Scientific Society), 766
Crucible, Torch and, the Life and Death of Antoine Lavoisier (Sidney F. French), *review*, 619
Crustacea (Decapod), Larvæ of (Dr. Robert Gurney), *review*, 474
Crystal Analysis, A New Synthesis of X-Ray Data for (Dr. H. Lipson), 25
Crystal Metal Points (Single), Autoelectronic Emission from (M. Benjamin and R. O. Jenkins), 295
Crystal Structure: of Cobalt (O. S. Edwards and H. Lipson), 295; (A. J. C. Wison), 295
  of Oxyhæmoglobin (M. F. Perutz), 324
Crystals: Raman's Theory of Specific Heat of (Dr. M. Blackman and Prof. M. Born), 55
  Temperature Variation of Diffuse Scattering of X-Rays by (Prof. M. Born and Dr. K. Lonsdale), 490
  (Metal), Elastic Constants of (K. Fuchs and H. W. Peng), 436
Cu_3Au, Order in the Alloy (L. H. Germer, F. E. Haworth and J. J. Lander), 238
Cuckoo Problems (E. C. Stuart Baker), *review* by Dr. F. H. A. Marshall, 221
Cultivation: and Crop Yields, Soil Physics, Soil Cultivation, and (Dr. B. A. Keen), 264
  (Biology and) of Oysters in Australia (G. Humphreys), 544
  Soil-less (Prof. R. H. Stoughton), 174
Cultural and Scientific Mission to China, 369, 426
Culture of the Ft. Liberté Region, Haiti (Irving Rouse), *review* by G. H. S. Bushnell, 103
Culture: (Artificial) of Datura Embryos (J. van Overbeek, M. E. Conklin and A. F. Blakeslee), 435
  (Artificial) of Prunus Hybrids (G. W. Skimm), 435
Cultures (Cave and Lake Bed) of South Central Oregon in the Northern Great Basin (L. S. Cressman), 157
Curriculum Reform, Science and, *review* by J. A. Lauwerys, 503
Cursor, The Slide Rule (W. R. Ashby), 379
Curve (Tolerance), Intravenous Glucose (G. D. Greville), 522
Customs (Marriage) in the Making, *review* by Mrs. S. Neville-Rolfe, 505
Cyanogen Criterion of Absolute Magnitude (Dorrit Hoffleit), 436
Cygni (1942), Nova (George Alter), 463
Cynic Science, *review* by Prof. John L. Myres, 164
Cytological Criteria of Mammalian Endocrine Activity (C. L. Foster), 279
Cytological Technique, New, *review* by Dr. Irene Manton, 102
Cytology and Cell Physiology (edited by Geoffrey Bourne), *review* by Dr. Irene Manton, 362
Cytoplasmic Inclusions in the Germ Cells of the Mouse (Dr. R. A. R. Gresson), 663
Cytoplasmic Organization, Native Proteins, Flexible Frameworks and (Dr. Dorothy Wrinch), 270
Czech Chemistry, The Mendeléeff-Brauner Tradition in (Dr. Gerald Druce), 623

DAFFODIL, Food Manufacture and Flowering in the (Dr. John Grainger), 232
Darvela near Truns, Description of four Skeletons from (Prof. Otto Schlaginhaufer), 150
Darwin: Marx, Wagner, Critique of a Heritage (Jacques Barzun), *review* by Prof. A. Wolf, 72; (Prof. Macgregor Skene), 150
  Manuscripts and Letters, 535
  Medal of the Royal Society awarded to Prof. D. M. S. Watson, 571, 665
Darwinian Exhibition in Moscow (Sir Arthur Keith), 393
Data: (Reaction), Energy-Level Treatment of (Dr. J. W. Baker), 551
  (Reference) for Radio Engineers (Standard Telephones and Cables, Ltd.), 346
Datura Embryos, Artificial Culture of (J. van Overbeek, M. E. Conklin and A. F. Blakeslee), 435
Datura stramonium (Nine Strikingly Diverse Types in) with Location of their Determiners in a Single Chromosome (Albert F. Blakeslee and A. G. Avery), 238
Davy Medal of the Royal Society awarded to Prof. C. N. Hinshelwood, 571, 665
D.C. (A.C. and) Peak-Factor Meter (E. H. W. Banner), 401
Decapod Crustacea, Larvæ of (Dr. Robert Gurney), *review*, 474
Defects in Glassware, 27
Defence (Civil) against War Gases, 642; (Prof. J. B. S. Haldane), 769
Defoliators (Shisham) in the Punjab Plantations, On the Biology of the Parasites of the (R. N. Mathur and C. F. C. Beeson), 552
Deformations, Table of (British Rheologists' Club), 602
Dehydration: Function of the Kidney in (D. A. K. Black, Dr. R. A. McCance and W. F. Young), 461
  of Foods and the Effect on their Nutritional Value (Nutrition Society, jointly with the Food Group of the Society of Chemical Industry, conference on), 54, 223
Dehydro-Ascorbic Acid, Use of Formaldehyde in the Estimation of Ascorbic Acid and (J. W. H. Lugg), 577
Delinquency, A Study of, *review* by Prof. Cyril Burt, 361
Deltaic Formation, with Special Reference to the Hydrographic Processes of the Ganges and the Brahmaputra (Strickland, Prof. C.), *review* by Sir Lewis Fermor, 67
Democracy? Is Britain a (Frank Hardie), *review*, 447
Democratic Idea, The (Francis Williams), *review*, 447
Dental Hygiene in Mexico, General Health and (Dr. Miguel E. Bustamante), 401
Deoxycholic Acid, Preparation of (Dr. G. A. D. Haslewood), 211
Depressor (Antipressor and) Effects of Oxidation Products of Pressor Amines (Dr. Kurt A. Oster), 289
Depths of the Arctic Ocean, 734
Derivation of Petroleum, *review*, 194
Derris and other Rotenone Bearing Vegetable Insecticides, their Occurrence and Possibilities of Cultivation in India, A Note on (T. P. Ghose), 609
Desert (Egyptian), Frequency of Dust-storms in the (Dr. H. Heywood), 293
Desiccation, Metabolic Water and (Dr. Kenneth Mellanby), 21
Design: (Engineering), Application of the Study of Vibration to, *review*, 392
  and Purpose (Prof. Frederic Wood Jones), *review* by Prof. A. D. Ritchie, 69
Designers (Students and), Materials for, *review*, 645
Desoxycorticosterone (Non-effect of Massive Doses of Progesterone and) on Lactation (Dr. S. J. Folley), 266
Detection of Cracks in Engineering Materials, 343
Detectors, Magnetic Crack, 344
Determination: of Absolute from Relative X-Ray Intensity Data (S. H. Yü), 151; (A. J. C. Wilson), 151
  (Micro-) of Calcium in Serum (P. F. Holt and H. J. Callow), 553
  of Equilibrium Diagrams by X-Ray Methods (Institute of Physics discussion on), 465
  of Moisture Content (Dr. L. G. G. Warne), 607
Development: (Canalization of) and the Inheritance of Acquired Characters (Dr. C. H. Waddington), 563
  (Growth and), Growing-Points in the Study of (Dr. Joseph Needham), 421
  (The Natural) of the Child (Dr. Agatha H. Bowley), *review* by A. W. Wolters, 749
Developmental Study of the Maize Shoot (B. C. Sharman), 435
Devonian (Lower) Plants, 352
Dialectic, Bradley's (Dr. Ralph Withington Church), *review* by Prof. W. G. de Burgh, 671
Diamonds, Absorption and Scattering of Light in (P. G. N. Nayar), 741
Diary, A Nature, *review* by Seton Gordon, 506
1:2:5:6-Dibenzanthracene, Formation of Hæmolymph Nodes in Rats treated with (Dr. A. Lasnitzki and Dr. D. L. Woodhouse), 660
Dicotyledon and Monocotyledon, Shoot Organization in, 95
Dictionary, Russian-English Technical (Sir John Russell), 58; (Kenneth Airy-Shaw and P. A. Dattan), 323
'Die-back' Disease of Apricots (H. Denham and H. Wormald), 630
Dietary (War-time), Mineral and Vitamin Requirements and the (Prof. R. A. Peters), 125
Diethyl Sulphide (Aniline,) and two Binary Liquid Mixtures, Raman Frequencies of (Dr. C. S. Venkateswaran and N. S. Pandya), 741
Diets (Highly Purified), Lactation and Reproduction on (Dr. S. J. Folley, Dr. K. M. Henry and Dr. S. K. Kon), 318
Differential Electronic Stabilizer for Alternating Voltages (Arvon Glynne), 740
Differential Equations, Linear, *review* by Prof. L. M. Milne-Thomson, 647
Diffraction: Electron (Prof. G. P. Thomson), 659
  Data (X-Ray), Index of (Sir Lawrence Bragg), 738
  of Ultra-Short Radio Waves (Dr. J. S. McPetrie and J. A. Saxton), 292
  (X-Ray), Theory of (Prof. P. P. Ewald), 450
Digestibility of High-Extraction Wheatmeals (T. Moran and J. Pace), 224
Digestive Assimilation of Starch and Cellulose in Herbivora, Microbial Factors in the (Frank Baker), 479
Dimensions (Dr. Norman Campbell), 89; (Prof. H. Dingle), 89; (Dr. G. B. Brown), 89
Dinosaur Find at Washington, D.C., 54
'Diphenylene', Structure of (Wilson Baker), 210; (Dr. C. A. Coulson), 577
Diploid Potato Species (Certain), Self-incompatibility in (G. P. Carson and H. W. Howard) 290
Dipper (Conveyor Belt), Seed Potato Disinfection by (C. T. N. Wakely and H. C. Mellor), 769
Direct Current (Static Conversion of) to Alternating Current with Grid-Controlled Mercury-Arc Mutators (R. Feinberg), 664
Discharge (High-Frequency), Selective Excitation of Spectra by the (Prof. R. K. Asundi and Nand Lal Singh), 123
Discipline: of Peace (K. E. Barlow), *review* by R. Brightman, 219
  (Academic), Sociology as an, *review* by Prof. George Catlin, 590
Discoveries by Accident (Prof. Sidney Russ), 735; (Prof. H. R. Robinson), 735
Discrimination Method in Animal Psychology (Dr. H. Honigmann), 296
Discussion Groups; Handbooks for, Nos. 1–4, *review*, 447
  How to Lead (E. M. Hubback), *review*, 447
Discussions on Citizenship, *review*, 447
Disease: and the Social System (Arthur Guirdham), *review* by Dr. H. G. Baynes, 247
  (Epidemic) in English Village Life in Peace and War (Dr. W. N. Pickles), 345
Diseases: of the Heart, History of, *review* by Sir Thomas Lewis, 561
  Potato Virus (F. C. Bawden), 476
  Venereal, a Sociological Problem, 529
Disinfection (Seed Potato) by Conveyor Belt Dipper (C. T. N. Wakely and H. C. Mellor), 7 9
Displacement Method of Weighing Living Organisms (A. G. Lowndes), 695
Dissociation of Carbon Monoxide, Energy of (Dr. A. G. Gaydon and Dr. W. G. Penny), 406
Distribution: of Population and the Location of Industry on Merseyside (W. Smith), 437
  of the Stars (Dr. Bart J. Bok), 459
  World Co-operation in Production, Consumption and, 387
Disturbances (Suppressing High-Frequency) from Telephone Apparatus (M. E. Krom), 265
Dock Aphides, Bean and, 294
Doctor, A Great Country (Prof. Charles Singer), 286
Documentation: in an Industrial Laboratory (Miss M. Shaw), 601
  and Microfilm, 601
Dolomite Bricks for use in Steelworks (T. Swinden and J. H. Chesters), 184
μ Draconis, New Companion to (Dr. K. Aa. Strand), 400
Drainage (Field), The Principles of (H. H. Nicholson), *review* by Dr. R. K. Schofield, 391
Dried Foods (Nutrition Society and the Food Group of the Society of Chemical Industry conference on), 54, 223
Driffield (Hurter and): Sensitometry since (Dr. S. O. Rawling), 519
  Memorial Lecture of the Royal Photographic Society to be delivered by Dr. S. O. Rawling, 519
Drifting Force on a Ship among Waves (T. E. Havelock), 352
Drosophila, Anemotaxis in (Dr. H. Kalmus), 405
Drosophila melanogaster, Homology of the Campaniform Organs on the Wing of (Dr. A. D. Lees), 375
Drugs: Control of Opium and other Dangerous, 370
  (Foods and), Aids to the Analysis of (Dr. J. R. Nicholls), sixth edition, *review* by J. H. Singer, 674
Drying Trials (Delayed) in Nigeria and Kenya, Results of, 439
Dugesia tigrina (syn. *Planaria maculata*), Sexuality in (Dr. E. D. Goldsmith), 351

Duplicating Foreign Periodicals, The Gesteprint Process for (H. J. Dowden), 601
Dust-storms in the Egyptian Desert, Frequency of (Dr. H. Heywood), 293
Dyeing with Coal Tar Dyestuffs (C. M. Whittaker and C. C. Wilcock), fourth edition, *review* by Dr. E. F. Armstrong, 618
Dyer Imparts his Knowledge, *review* by Dr. E. F. Armstrong, 618
Dynamics of a Spinning Top (J. Miller), 436

Eadarloch, Loch Treig, The Lake-dwelling or Crannog in (Prof. James Ritchie), 639
Early Horizons: in the Southeast (Prof. William S. Webb), 156
    in the Southwest, Discoveries in Sandia Cave and (Frank C. Hibben), 156
Earth: Biography of the (Prof. George Gamow), *review* by Prof. A. Holmes, 391
    The Figure of the (Royal Astronomical Society Geophysical discussion on), 339
    Heat Energy from Radioactive Sources in the (William D. Urry), 30
Earthed-Plate Amplifier for the Frequency-Modulation Transmitter (A. A. Skene), 438
Earthing, Protective Multiple, 272
Earthquake at Lewiston, Maine, on March 8, 1942 (William H. Weeks), 238
Earthquake (New Hampshire) of 1940. Cause of the, 300
Earthquake Activity in New Zealand, 243
Earthquake Records, Recent, 401
Earthquake Swarm in the Azores, 488
Earthquakes :—
    at Acari on August 24, 288
    in Albania, 288
    at Almora, India, on October 10, 488
    in Central America on August 6 and August 8, 518; in South America on May 14, 118
    in Anatolia on December 3, 687
    south-west of Antigua on August 6 and August 8, 518
    in the Balkans on August 27, 2 8, 345
    north-west of Basel on July 18, 545
    registered at Berkeley, California, on November 10, 602
    in the Berneroberland between Simmental and Kandertal on February 17, 175
    in the Bodenunruhe on February 28, 175
    in the Brünig and Lungernsee on August 27, 545
    in Southern California on October 21, 687
    in Chile on June 29, 54; on July 8, 632
    near the coast of Ecuador on July 8 and July 12, 632; off the coast of northern Ecuador in July, 345
    in Guatemala, 518
    in the Hohenstollen on August 28, 545
    at Hokitika on June 25, 459
    in the Udine Province of Italy on April 12, 175
    at Karachi on July 3, 54
    registered at Kew on July 12, 150; on August 7, 207; during October, 602
    at Mürtschenstock, Switzerland, on June 25, 345
    at Nazca on August 24, 288
    south-east of the Neuenburgersee on March 15, 175
    in the New Guinea region on June 6, 459
    registered in New Zealand during March, 18 ; during April, 119 ; on June 14, 119 ; on June 24, 18 ; during June, 459 ; during August, 659
    in Nicaragua (south of the Golfo de Fonseca) on September 26, 687
    in the Pacific Ocean (off the Coast of Chile) on July 8, 345; in the Pacific Ocean (between Kamchatka and the Aleutian Islands) on August 23, September 2, 4 and 9, 632 ; in the Pacific Ocean (off Central America) on August 6 and September 4, 632
    in the Pays d'Enhaut on July 1, 545
    in southern Peru on August 24, 288, 345 ; near the coast of Peru on August 24, 632
    near the Presse Griechenland on June 1, 345
    south-east of Rancagua, Chile, on June 29, 207
    Recent, 207, 288, 345, 488, 602, 632, 687
    in the Rheintalgraben to the south of Freiburg on February 6, 175
    in the Schwäbische Alb on July 17, 545
    in Spain on July 12, 118
    in the Stuttgart Rheintalgraben on February 22, 175
    registered in Switzerland during February, March, April and May, 175; registered in Switzerland, 545 ; reported from Switzerland on October 30, 602
    in the Songea District, Tanganyika, on November 8, 602
    at Trentino, Italy, on June 20, 345
    in Western Turkey on October 29, 632
    near Venice on February 7, 175
    at Wairarapa on June 24, 459
    in the Westalpen east of the Pelvoux-Massiv on February 12, 175
Earthquakes : in New Zealand (Dr. J. Henderson and R. C. Hayes), 554
    in the United States during 1939 (Ralph R. Bodle), 239
    (Mechanics of) where there is no Surface Faulting (L. Don Leet), 300
Eclipse: (Total) of October 1, 1940, Spectrographic Observations at the (R. O. Redman), 353
    (Total Solar) of October 1, 1940 (Dr. A. Hunter), 512
Econometrics, A Problem in, *review* by Dr. A. L. Bowley, 335
Economic Forces and World Order, *review* by G. D. H. Cole, 69
Economic Foundations of a New World Order, 33
Economic Time Series, The Analysis of (Harold T. Davis), *review* by Dr. A. L. Bowley, 335
Economic Value of the Common Stinging Nettle (Dr. C. R. Metcalfe), 83
Economics: An Introduction to, *review* by G. D. H. Cole, 617
    of 1960 (Colin Clark), *review* by G. D. H. Cole, 69
Economy: in the Use of Ferro-Alloys (Dr. W. H. Hatfield), 509
    (Post-war), General Principles of a (London Chamber of Commerce), 33
Ecuador: Earthquake of May 14, 118
    (near the coast of), Earthquakes on July 8 and July 12, 632
    (off the coast of Northern), Earthquakes in July, 345
Education: in the New Order (Miss Knight-Bruce), 399
    Science and (John Case), 236; (S. R. Humby and Dr. E. J. F. James), *review* by J. A. Lauwerys, 503
    Social Biology in (British Social Hygiene Council conference on), 555
    and Leadership in the Women's Services, 415
    and Training of Physicists (Institute of Physics discussion on), 429, 568; (J. A. Crowther), 568
    after the War (M. L. Jacks), 168

    (University), Future of, 716
Educational Biology (Hugh Ramage), 542
Educational Trust, Formation of a National Veterinary, 500
Eels (British), The Freshwater Life of (Miss Winifred Frost), 493
Efficiency: Color for (Matt. Denning and Arthur A. Brainerd), 19
    (Workshop), Colour of Machines and, 19
Eggs: Hatching of (R. K. Cole), 237
    from the Fallopian Tube of the Rat, Collection of (I. W. Rowlands), 267
Egypt, Star Atlas for the Latitude of (H. E. Hurst, M. R. Madwar and A. H. Samaha), second edition, 764
Egyptian Desert, Frequency of Dust-storms in the (Dr. H. Heywood), 293
El Salvador, Tuberculosis in (Dr. Rafael Vega Gomez), 264
Elastic Constants of Metal Crystals (K. Fuchs and H. W. Peng), 436
Electric Generator, A 1000-kw. Wind-driven, 207
Electric Motors, Overheating of, 287
Electric Strength (Intrinsic) and Conductivity of Varnish Films and their Variation with Temperature (A. Morris Thomas and Miss M. V. Griffith), 770
Electrical Contact Effects, Analysis of, 743
Electrical Engineering: (W. Tolmé Maccall), Vol. 2, *review*, 222
    in the United States (Archer E. Knowlton), 31
Electrical Engineers and the Post-War Period (Prof. C. L. Fortescue), 467
Electrical Equipment of Buildings (Institution of Electrical Engineers War Emergency Relaxations of the Regulations for the), eleventh edition, 119
Electrical Instruments, Standardization of Industrial (Lieut.-Col. K. Edgcumbe), 734
Electrical Joints, Soldering, 371
Electrical Production of Bullet-proof Steel (A. G. Arend), 298
Electrical Properties of Polystyrene (F. T. Farmer), 521
Electrically Heated Hotbeds, Simplified (C. A. Cameron Brown and E. W. Golding), 659
Electricity: (Application of) to the Annealing of Glass Bottles and Containers (E. S. Morris), 400
    in a Beet-Sugar Factory (B. Smith), 344
    (Domestic) Supply, Optional-Control System of (P. Schiller), 53
Electricity Commissioners' Overhead Line Regulations El.C.53, suggested amendment of the (J. McCombe), 345
Electrification (Rural) and Research (A. G. H. Dent), 344
Electrified Cane-Sugar Factory (L. B. Whitaker), 344
Electrode Potential (Iron) in a Magnetic Field (A. L. Parson), 605
Electromagnetic Waves in Metal Tubes of Rectangular Cross-section (J. Kemp), 32
Electromagnetic-Hydrodynamic Waves, Existence of (Dr. H. Alfvén), 405
Electron Diffraction (Prof. G. P. Thomson), 659
Electron Lenses (Dr. D. Gabor), 650
Electronic Charge, Measurement of (Prof. T. H. Laby), 648
Electronic Relay Control (St'r Electronic Controls), 345
Electronic Stabilizer (Differential) for Alternating Voltages (Arvon Glynne), 740
Element 85 in the Thorium Family, Experimental Evidence of the Existence of (Mrs. Alice Leigh-Smith and Dr. Walter Minder), 767
E.M.F. of Thermal Fluctuations in Resistances (M. Surdin), 550
Emission : (Absorption and) of Radiation in the Atmosphere, 144
    (Autoelectronic) from Single Crystal Metal Points (M. Benjamin and R. O. Jenkins), 295
Empire Relations (Peter Le Neve Foster lecture by Viscount Bennett), 370
Employment : (Full), After the War— (A. H. Hansen), 457
    Part-time (F. C. Hooper), 17
Enamel Organ of the Rat's Incisor Tooth in Vitamin E Deficiency (Prof. J. T. Irving), 122
Encouragement of Research in Industry (Philip R. Coursey), 374
Endocrine Activity, Cytological Criteria of Mammalian (C. L. Foster), 279
Endocrinology, Institute of, at Montevideo, 207
Enemy Prisoners of War, Scientific Literature for (Dr. John R. Baker), 408
Energy : of Dissociation of Carbon Monoxide (Dr. A. G. Gaydon and Dr. W. G. Penney), 406
    (Heat) from Radioactive Sources in the Earth (William D. Urry), 30
Energy-Level Treatment of Reaction Data (Dr. J. W. Baker), 551
Engine, The High-Speed Compression-Ignition (C. B. Dicksee), *review* by Prof. S. J. Davies, 752
Engineering : In Agriculture (Sir John Thornycroft), 542
    Cadetships, 543
    Design, Application of the Study of Vibration to, *review*, 392
    Kinematics (Prof. Alvin Sloane), *review*, 73
    Materials, *review* by Dr. E. H. Tripp, 195
    Materials, Detection of Cracks in, 343
    Mechanics (Prof. S. Timoshenko and Prof. D. H. Young), second edition, *review*, 73
    Optics Applied to (K. J. Habell), 53
    Pedagogy, *review*, 73
    (Agricultural), National Institute of, 87
    (Chemical) at Leeds, 53
    (Chemical), Thermodynamics and, *review* by Prof. D. M. Newitt, 37
    (Civil) and the Building Industry (Institution of Civil Engineers discussion meetings on), 288
    (Electrical) (W. Tolmé Maccall), Vol. 2, *review*, 222
    (Electrical) in the United States (Archer E. Knowlton), 31
Engineers (Electrical) and the Post-War Period (Prof. C. L. Fortescue), 467
Engineers (Radio), Reference Data for (Standard Telephones and Cables, Ltd.), 346
England, Constructional Elements in the Physiography of the Southern Counties of (F. Owen Whitaker), 242
England and Wales, Land Utilization in, 448
English Countryside, The, 441
English Social Stratification, Psychological Aspects of (Prof. T. H. Pear), 465

English Village Life in Peace and War, Epidemic Disease in (Dr. W. N. Pickles), 345
English (Russian-) Technical Dictionary (Sir John Russell), 58 ; (Kenneth Airy-Shaw and P. A. Dattan), 323
English (Russian-) Technical Glossaries, 543
Enolization (Photo-) of Ketones (T. Iredale), 579
Entomology, Outlines of (Dr. A. D. Imms), *review* by Dr. V. B. Wigglesworth, 505
Enzyme: from Kidney on the Solubility of Calcium Phosphate, Effect of an (Dr. H. Lehmann), 603
  Concentration, A Simple Method for (Jacob Feigenbaum), 318
Enzyme-Substrate Combination ? Is Muscle Contraction essentially an (Dr. Joseph Needham, Dr. Arnošt Kleinzeller, Miss Margaret Miall, Mrs. Mary Dainty, Dr. Dorothy Needham and Dr. A. S. C. Lawrence), 46
Enzymes (Respiratory), A Symposium on, *review* by Dr. F. Dickens, 277
Epidemic Disease in English Village Life in Peace and War (Dr. W. N. Pickles), 345
Epithelium (Ciliated) of the Frog's Mouth, Demonstration of Action of (G. B. West), 580
Equations, Linear Differential, *review* by Prof. L. M. Milne-Thomson, 547
Equilibrium Diagrams (Determination of) by X-Ray Methods (Institute of Physics discussion on), 465
Equines, Non-bacterial Abortion in (V. R. Rajagopalan), 231
Equipment (Electrical) of Buildings (Institution of Electrical Engineers War Emergency Relaxations of the Regulations), eleventh edition, 119
Errors in Mathematical Tables (Dr. L. J. Comrie), 738
Eskimo, The Problem of the (Dr. Aleš Hrdlička), 155
Ester Hydrolysis (G. R. Lucas and L. P. Hammett), 609
Ethical Ideals in India To-day (Dr. Edward Thompson), *review* by Dr. Mulk Raj Anand, 131
Ethnographic Bibliography of North America (George Peter Murdock), *review* by Mrs. K. Rishbeth, 619
Euglandina rosea (Férussac), Food; Eggs and Young of the Carnivorous Snail (William Marcus Ingram), 663
Euplotes patella, Genetics of Mating in (R. F. Kimball), 295
Europe : Medical Relief in (Dr. M. D. Mackenzie), 288
  Organization of Post-War Relief in, 305
  Post-war Reconstruction of Agriculture in, appointment of a British Association Committee to collaborate with the Allied Technical Advisory Committee on scientific problems connected with the, 346
  Relief and Reconstruction in (Royal Institute of International Affairs report on), 305
  and Middle East, Map of (British Council), 543
European Allies, Reconstruction Research conducted in Britain by the (Ethel J. Lindgren), 457
Evolution : Administrative Service or Tyranny?, *review* by R. Brightman, 501
  in the Horse's Skull (E. C. R. Reeve and P. D. F. Murray), 402
  the Modern Synthesis (Dr. Julian Huxley), *review* by Dr. W. B. Turrill, 747
  in Society, 527
Excavations : in the Ft. Liberté Region, Haiti (Froelich G. Rainey), *review* by G. H. S. Bushnell, 103
  at Ras Shamra (Commander Schaeffer), 327
  in Transcaucasia (Prof. B. A. Kuftin), 28
Excitation (Selective) of Spectra by the High-Frequency Discharge (Prof. R. K. Asundi and Nand Lal Singh), 123
Excretion (Glucose) by the Rabbit Kidney (Prof. T. W. T. Dillon), 492
Exhibitions: (Darwinian) in Moscow (Sir Arthur Keith), 393
  of Photography in Science and Industry, 519
  of Photography's Part in the War, 519
  (Scientific) in Moscow, 369
  of Soviet Life in War and Peace, 519
Existence of Electromagnetic-Hydrodynamic Waves (Dr. H. Alfvén), 405
Exploitation of Minerals in relation to National and World Planning (Dr. L. Dudley Stamp), 395
Explosives (Prof. John Read), *review* by Dr. E. F. Armstrong, 561
Eye in Industry (Institute of Physics (London Branch) Conference on), 80
Eye-movement, Genetics and (H. E. Jones and D. H. Morgan), 552

FACTOR : (Personal) in Accidents (Industrial Health Research Board, Emergency Report No. 3), 396
  (Thermal Diffusion), Change of Sign of the (K. E. Grew), 320
Factors (Microbial) in the Digestive Assimilation of Starch and Cellulose in Herbivora (Frank Baker), 479
Factory Department, Report of the Chief Inspector for 1941, 557
Factory Inspection in Great Britain (Dr. T. K. Djang), *review* by R. Brightman, 390
Fair Shares for All (Political and Economic Planning Broadsheet No. 192), 629
Fallopian Tube of the Rat, Collection of Eggs from the (I. W. Rowlands), 267
False-Ring Pattern in Larch (Dr. C. G. Dobbs), 377
Family : Nutrition and Size of, Report on a New Housing Estate, 1939 (Prepared for the Birmingham Social Survey Committee by M. S. Soutar, Dr. E. H. Wilkins and Dr. P. Sargant Florence), *review*, 475
  Size and Survival in Great Britain (Dr. Percy Stocks), 597
  (Marriage and) in Mysore (M. N. Srinivas), *review* by Mrs. S. Neville-Rolfe, 505
Farming : in Great Britain, 518
  Handbook (Sir E. J. Russell, Dr. H. D. Kay, Dr. W. G. Ogg, B. T. P. Barker, Malcolm Messer, Geoffrey Browne, F. H. Garner, J. A. McMillan, T. Nellist Wilks, Dr. E. Holmes, W. R. Orrell, and other Experts), *review*, 618
  (War-time) in Britain, *review*, 618
  (War) and After (Lord Cornwallis), 518
Fat in Animals and Plants, Rapid Determination of (A. G. Lowndes), 291
Fatty Acid Derivatives in Living Tissues, The Mode of Occurrence of (J. A. Lovern), 294
Faulting (Surface), Mechanics of Earthquakes where there is no (L. Don Leet), 300
Fauna: (Insect) of a Brine-Pit (Frederick Burke), 610
  (Insect) of Lower California (A. E. Michelbacher and E. S. Ross), 552; (E. Gordon Linsley), 552; (E. C. Van Dyke); 552; (A. E. Michelbacher and T. H. G. Aitken), 552
  (Marine) of Bristol Channel (R. Bassindale), 435
Feedback Amplifiers (C. A. A. Wass), 381
Feeding: of the Common Toad (O. R. Barclay), 376
  and Breeding of *Calanus finmarchicus*, On the (J. E. Raymont and Dr. F. Gross), 327
Fermentation: (Bacterial), Potassium in (Dr. J. Leibowitz and N. Kupermintz), 233
  (Potassium) and the Cell Membrane (Prof. Edward J. Conway), 461
Ferro-Alloys, Economy in the Use of (Dr. W. H. Hatfield), 509
Fertility, Registrar-General's First Report on, 597
Fertilization, Rôle of Hyaluronidase in (Dr. D. McClean and Dr. I. W. Rowlands), 627
Fertilizer from Urban Wastes, Manufacture of (George Bransby Williams), 299
Fevers in the Sudan, 631
Fibres (Animal), Scaliness of (N. H. Chamberlain and Prof. J. B. Speakman, 546
Field Drainage, The Principles of (H. H. Nicholson), *review* by Dr. R. K. Schofield, 391
Figure of the Earth (Royal Astronomical Society Geophysical discussion on the), 339
Films (Scientific): Conference on, 230
  and their Use in the Teaching of Physics (Physical Society discussion on), 691
  (Soviet), 342
Films (Varnish) and their Variation with Temperature, Intrinsic Electric Strength and Conductivity of (A. Morris Thomas and Miss M. V. Griffith), 770
Filters, Junction Line (F. A. Hinshaw), 159; (J. O. Israel), 159
Finance and Social Service in Great Britain, 629
Financial Mysticism (Political and Economic Planning Broadsheet No. 188), 629
Finishes (Industrial), Infra-red Baking of (H. Seymour), 371
Fire Service (National), Man-Power in the, 354
Fires, Smoke from their, the Life of a Kwakiutl Chief (Prof. Clennan S. Ford), *review* by Mrs. K. Rishbeth, 193
Fish: in Australia, Refrigeration of, 458
  (St. Peter's) in Lake Huleh, Palestine, Death of (Dr. C. K. Ricardo Bertram), 58
Fisheries, Californian, report for the Year 1940, 53
Fishery (Galway), History of the (Arthur E. J. Went), 572
Fishes: Freshwater, 493
  New and Little-known, 639
  Studies of South American Freshwater (George G. Myers), 639
Fixing Smoked Tracings, A Varnish for (G. B. West), 769
Flame Gas Temperatures, Influence of Water Vapour on (Prof. W. T. David and J. Mann), 521
Flame Gases, Abnormality of (Prof. W. T. David), 320
Flames, Radiation from (Prof. W. T. David), 407
Flight of Pure Imagination (Sir Charles V. Boys), 464
Flora: (North American), Discovery of the, 89
  of late Lower Old Red Sandstone Age in Britain (W. N. Croft and W. H. Lang), 352
Floras (Yorkshire), A Supplement to the (the late F. Arnold Lees), *review*, 8
Florida, New Species of Fungi from (Wm. A. Murrill), 609
Flour: (National) and Bread, Second Report, 538
  (High B_1 White), Heterogeneity in Wheat Germ and, 608
Flour Beetle (American) *Tribolium confusum* Duval, Vitamin Requirement of the (H. Rosenthal and T. Reichstein), 546
Fluorescence: of Uranyl Compounds (B. S. Satyanarayana), 741
  Light Scattering and the Raman Effect, Symposium on, 741
Fluorides (Complex), Structure of (J. L. Hoard and M. B. Williams), 27
Fluxmeter, A Magnetic (E. L. Norton), 355
Folding of the Selenanthren Molecule (Raymond G. Wood and Gordon Williams), 321
Folk-Lore: Ophthalmic (Dr. J. D. Rolleston), 573
  Otology and (Dr. J. D. Rolleston), 496
  Treatment of Sneezing (Dr. Leo Kanner), 118
Folsom and Yuma Problems (Edgar B. Howard), 157
Food (Tea Leaves as a Maintenance) for Animals (W. King Wilson), 199
Food and Planning (Prof. J. R. Marrack), *review* by Prof. A. St. G. Huggett, 729
Food Storage and Transport, 217
Food Value of the Potato, 518
Foods: (Dehydration of) and the Effect on their Nutritional Value (Nutrition Society, jointly with the Food Group of the Society of Chemical Industry, conference on), 54, 223
  (Dried), Nutrition Society and the Food Group of the Society of Chemical Industry conference on, 54, 223
Foods and Drugs, Aids to the Analysis of (Dr. J. R. Nicholls), sixth edition, *review* by J. H. Singer, 674
Foot-and-Mouth Disease, Starlings and (Dr. W. S. Bullough), 739
Foraminifera of the Tropical Pacific (J. A. Cushman), 182
Forbes, 1929 II, Periodic Comet, 232
Force (Drifting) on a Ship among Waves (T. E. Havelock), 352
Forest Administration in the Province of Assam for the year 1940–41, Report of (C. Mackarness), 440
Forest Research in India and Burma, 1940–41, Part I: The Forest Research Institute, 215
Forest Soils (Brazilian), Water Reserves in (Felix Rawitscher), 183
Forest Utilization (Indian), Manual of (H. Trotter), *review* by B. J. Rendle, 167
Forestry: in Assam, 440
  (Sampling Methods in) and Range Management (F. X. Schumacher and R. A. Chapman), *review* by Prof. R. A. Fisher, 196
Forestry Research: in Africa, Commission of (E. N. Corbyn), 379
  Indian, 215
Forests of Latin America, Potentialities of the (Prof. S. J. Record), 89
Form, On Growth and (Sir D'Arcy Wentworth Thompson), revised and enlarged edition, *review* by Dr. Harold Jeffreys, 332
Formaldehyde in the Estimation of Ascorbic Acid and Dehydro-Ascorbic Acid, Use of (J. W. H. Lugg), 577
Ft. Liberté Region, Haiti: Culture of the (Irving Rouse), *review* by G. H. S. Bushnell, 103
  Excavations in the (Froelich G. Rainey), *review* by G. H. S. Bushnell, 103

Fossil Lamellibranchs (Small), Optical Projection as an Aid in Studying Plane Spiral Coiling of (Lieut. A. T. J. Dollar), 57
Foster (Peter Le Neve) Lecture on Empire Relations (Viscount Bennett), 370
Foundations: for a Science of Personality (Dr. Andras Angyal), *review* by J. Drever, 418
    (Economic) of a New World Order, 33
Framework, The Social, an Introduction to Economics (Prof. J. R. Hicks), *review* by G. D. H. Cole, 617
Frameworks (Native Proteins, Flexible) and Cytoplasmic Organization (Dr. Dorothy Wrinch, 270
Franklin Medal of the American Philosophical Society awarded to Dr. Sylvanus G. Morley, 155
Free German Institute to be founded by the Free German League of Culture in Great Britain, 54
Free Radical Chain Reactions (J. R. E. Smith and Prof. C. N. Hinshelwood), 295
Freedom, its Meaning (Benedetto Croce, Charles A. Beard, Jacques Maritain, Bertrand Russell, Gaetano Salvemini, Vilhjalmur Stefansson, Henry A. Wallace, Henri Bergson, Alfred North Whitehead, Thomas Mann, Felix Bernstein, Harold J. Laski, John Macmurray, Albert Einstein, J. B. S. Haldane, Lancelot Hogben, Frank Kingdon, Franz Boas, John Lewey), (planned and edited by Ruth Nanda Anshen), *review* by Prof. A. D. Ritchie, 100
Frequency (Change of), Reflexion of X-Rays with (Sir C. V. Raman), 366
Frequency-Modulation Transmitter, Earthed-Plate Amplifier for the (A. A. Skene), 438
Frequency Stability of Tuned Circuits (C. W. Eggleton), 765
Freshwater Fishes, 493
Freshwater Life of British Eels (Miss Winifred Frost), 493
Friction (Metallic), Mechanism of (Dr. F. P. Bowden and D. Tabor), 197; (Dr. J. E. Hurst), 349
Frictional Properties of Bearing Metals (J. L. Heaton, J. R. Bristow, G. Whittingham and Dr. T. P. Hughes), 520
Friendship (Inter-American) through the Schools (U.S. Office of Education, Bulletin No. 10, 1941), 54
Fritillaria meleagris, Localized Chiasmata in (H. N. Barber), 26
Frost in Pears, Parthenocarpy Induced by (D. Lewis), 608
Fruit, Hormone Sprays for, 19
Frog's Mouth, Demonstration of Action of Ciliated Epithelium of the (G. B. West), 580
Fuel (The Inter-Relation of Clothing and the Shortage of) in Matters of Health (Sir Leonard Hill), 346, 536
Fuel Shortage (Clothing and) on Health, Effects of (Sir Leonard Hill), 346, 536
Fulmar in the British Isles, The (Seton Gordon), 313
Fulmar (*Fulmarus glacialis*) in the British Isles, The Breeding, Distribution, History and Population of the (James Fisher and George Waterston), 313
Fumigation (High-Concentration Hydrogen Cyanide) of Fungi and Bacteria (Dr. N. Polunin), 682
Function: of the Kidney in Dehydration (D. A. K. Black, Dr. R. A. McCance and W. F. Young), 461
    of Soil Cracks (Dr. A. Sreenivasan), 409
Functions: of the Research Associations (Dr. F. C. Toy), 373; (Sir Lawrence Bragg), 373; (Philip R. Coursey), 464
    of Works Managers (Ernest Bevin), 229
Fundamentals of Vibration Study (R. G. Manley), *review*, 392
Fungi: New Species of (T. Petch), 352; (Elizabeth G. Gray), 352
    and Bacteria, High-Concentration Hydrogen Cyanide Fumigation of (Dr. N. Polunin), 682
    and the Biology of Man (Dr. J. Ramsbottom), 242
    from Florida, New Species of (Wm. A. Murrill), 609
Fungicides (Insecticides and), Committee to advise on the Official Recommendation of, 487
Future of University Education, 716

GALACTIC Clusters: in relation to the Galaxy (George Alter), 740
    Structure of (George Alter), 664
Galactic Pole, The True (O. R. Walkey), 183
Galaxies, Structure and Rotation of (Dr. A. Hunter), 169
Galaxy: Galactic Clusters in relation to the (George Alter), 740
    Motion of the Sun in the (Ralf E. Wilson), 400
Galileo, Newton and Halley, 483
Galway Fishery, History of the (Arthur E. J. Went), 572
Ganges Delta, Formation of the, *review* by Sir Lewis Fermor, 67
Gas Industry in Great Britain after the War, 95
Gas (Flame) Temperatures, Influence of Water Vapour on (Prof. W. T. David and J. Mann), 521
Gases, The Condition of Freshly Burnt (Dr. A. G. Gaydon), 481, 636; (Prof. W. T. David), 636
    (Flame), Abnormality of (Prof. W. T. David), 320
    (Hot), Luminous Radiation from (Prof. W. T. David), 291
    (War), Civil Defence against, 642; (Prof. J. B. S. Haldane), 769
Gearing (Reduction) for Marine Steam Turbines (Dr. S. F. Dorey), 232
Genetic Classification of Brassica Crops (P. T. Thomas and M. B. Crane), 431
Genetics: of Mating in *Euplotes partella* (R. F. Kimball), 295
    for Medical Students (E. B. Ford), *review* by Dr. F. W. Sansome, 222
    of Natural Population (C. Epling and T. H. Dobzhansky), 237
    of the Sorghums (G. N. Ayyangar), 663
    Biochemistry and (E. L. Tatum and G. W. Beadle), 552
    and Eye-movement (H. E. Jones and D. H. Morgan), 552
Geographical and Geological Research in the U.S.S.R., 764
Geography (Social) in India, *review* by Prof. H. J. Fleure, 334
Geological Making of India (Sir Lewis Fermor), 725
Geological (Geographical and) Research in the U.S.S.R., 764
Geologists in War-Time (Dr. Bernard H. Knight), 25
Geology: in China (Prof. P. G. H. Boswell), 649
    (Chinese) during the past Twenty Years, Progress in (Dr, J. S. Lee), 649
    of the U.S.S.R., 487
    Romantic, *review* by Prof. A. Holmes, 391
Geomagnetism, Variations of (H. D. Harradon), 232
Germ Cells of the Mouse, Cytoplasmic Inclusions in the (Dr. R. A. R. Gresson), 663
German Baroque Literature, Magic and Natural Science in (Frederick Herbert Wagman), *review*, 619
Germination and Seedling Growth, Effect of the Moon on (M. Mather), 630
Gesteprint Process for duplicating Foreign Periodicals (H. J. Dowden), 601
Ghost Formation: on Absorption from Subcutaneously Implanted Tablets of Hexœstrol, Retarding Effect of (Dr. S. J. Folley), 735
    in Subcutaneously Implanted Tablets of Synthetic Œstrogens (Dr. S. J. Folley), 403
Glass (Optical), Manufacture of (H. W. Lee), 214
Glass Bottles and Containers, Application of Electricity to the Annealing of (E. S. Morris), 400
Glassware: Defects in, 27
    Cords, Surface Finish and the Quality of (A. J. Holland, Eric Preston and Prof. W. E. S. Turner), 27
Glazes (Insulator) on Porcelain, Influence of (E. Rosenthal), 771
'Glo-Crack' system of fluorescent light in the detection of cracks in engineering materials, 343
Globe, Iso-Magnetic Charts of the (W. M. Witchell), 439; (Prof. Sydney Chapman), 439
Glossaries, Russian-English Technical, 543
Glucose Excretion by the Rabbit Kidney (Prof. T. W. T. Dillon), 492
Glucose Tolerance Curve, Intravenous (G. D. Greville), 522
Glucose-aerodehydrogenase (Notatin, an Antibacterial) from *Penicillium notatum* Westling (C. E. Coulthard, Dr. R. Michaelis, Dr. W. F. Short, G. Sykes, G. E. H. Skrimshire, A. F. B. Standfast, Dr. J. H. Birkinshaw and Dr. H. Raistrick), 634
Glycerol (Production of) by Fermentation, Abstracts of Articles and Patents on the (National Research Council of Canada), 545
Goethe on Nature and on Science (Sir Charles Sherrington), *review* by Prof. E. N. da C. Andrade, 275
Goethe Prize of the city of Frankfurt-a.-M., awarded to Prof. Richard Kuhn, 573
Goethe's Science, *review by* Prof. E. N. da C. Andrade, 275
Goitrogenic Substances, Thio-Ureas as (T. H. Kennedy), 233
Golden Hamster as a Test Animal for Tubercular Infection (Dr. J. Ungar), 432
Gorgonorhynchus bermudensis n.sp., Notes on Bermudan Nemerteans (Dr. J. F.-G. Wheeler), 583
Government Chemist (Department of the), Centenary of the Government Laboratory (Dr. A. G. Francis), 567
Government and Industry, their Future Relations (Samuel Courtauld), 331
Government Laboratory, Centenary of the, Department of the Government Chemist (Dr. A. G. Francis), 567
Gran Chaco, Life among the South American Indians of the (Sir John Graham Kerr), 555
Granada, Earthquake on July 12, 118
'Granite Axial Core' of the Himalaya, The So-called (Major N. E. Odell), 379
Graph, The Saqqara, its Geometrical and Architectural Significance (R. S. Williamson), 460, 607
Grass, Back to Better (I. G. Lewis), *review*, 392
Grasses and Cereals, Onset of Reproductive Phase in (Dr. B. C. Sharman), 208
Gravitational Theory of Planetary Rotation (J. Miller), 215
Gravity Measurements in Guatemala (F. E. Wright), 352
Great Barrier Reef Bores (H. C. Richards and Dorothy Hill), 739
Great Britain: Cancer Research in (Dr. E. Boyland), 81
    Factory Inspection in (Dr. T. K. Djang), *review* by R. Brightman, 390
    Family Size and Survival in (Dr. Percy Stocks), 597
    Farming in, 518
    Finance and Social Service in, 629
    Future of the Population of (Colonel Sir Charles Arden-Close), 140
    Health Education in, 652
    Industrial Reconstruction in, 657
    Public Health in (Sir George Newman), 599
    The Public Schools in (Prof. J. D. Bernal, Prof, P. G. H. Boswell, Prof. S. Brodetsky, Prof. J. Chadwick, Prof. W. E. Le Gros Clark, Brig.-General F. A. E. Crew, Prof. C. Lovatt Evans, Prof. B. Farrington, Prof. C. E. Fawcett, Prof. P. Sargant Florence, Prof. P. F. Frankland, Prof. Lancelot Hogben, Prof. Julian Huxley, Dr. R. K. Kelsall, Prof. R. D. Laurie, Dr. Joseph Needham, Prof. R. Pascal, Prof. J. A. Ryle, Dr. F. Soddy, Dr. H. G. Stead, Prof. Geo. Thomson, Prof. F. H. Weiss, Prof. F. Wood-Jones), 351; (Prof. N. K. Adam), 433; (Rev. Canon Spencer Leeson), 524
    Rebuilding, 410
    Reconstruction in: The People, 685; The Land, 685; International Aspects, 685
    War-time Transport in, 611
    (The Gas Industry in) after the War, 95

Hybrids (Intergeneric) of Saccharum (E. K. Janaki-Ammal), 739
Hydrodynamic (Existence of Electromagnetic-) Waves (Dr. H. Alfvén), 405
Hydrogen Cyanide (High-Concentration) Fumigation of Fungi and Bacteria (Dr. N. Polunin), 682
Hydrogen Ions, their Determination and Importance in Pure and Industrial Chemistry (Prof. Hubert T. S. Britton), third edition, *review* by Prof. H. L. Riley, 534
Hydrolysis, Ester (G. R. Lucas and L. P. Hammett), 609
Hygiene (General Health and Dental) in Mexico (Dr. Miguel E. Bustamante), 401

ICE on Conductors, 345
Iceland, Health of, 573
Ideals (Ethical) in India To-day (Dr. Edward Thompson), *review* by Dr. Mulk Raj Anand, 131
Identification of Timbers, Studies of the (Alexander L. Howard), *review* by Dr. C. R. Metcalfe, 533
Ignition (The High-Speed Compression-) Engine (C. B. Dicksee), *review* by Prof. S. J. Davies, 752
Illumination and Visual Range under Water (Dr. H. H. Poole), 337
Imagination (Pure), A Flight of (Sir Charles V. Boys), 464
Immunity against Animal Parasites (Prof. James T. Culbertson), *review* by Lieut.-Colonel F. Murgatroyd, 360
Impact of Science on Agriculture (Sir John Russell), 311
Impregnating Varnishes (W. J. Kiernan), 544
Index: to Colour, A Popular, *review* by Dr. Sampson Clay, 70
  of X-Ray Diffraction Data (Sir Lawrence Bragg), 738
  (Subject) to Periodicals, 1940, *review*, 8
India: Earthquake at Almora, U.P., on October 10, 488
  Earthquake at Karachi on July 3, 54
  Geological Making of (Sir Lewis Fermor), 725
  A Note on Derris and other Rotenone Bearing Vegetable Insecticides, their Occurrence and Possibilities of Cultivation in (T. P. Ghose), 609
  Making of (D. N. Wadia), 726
  Mother-right in (Baron Omar Rolf Ehrenfels), *review* by Prof. J. H. Hutton, 644
  The Old and the New in, *review* by Dr. Mulk Raj Anand, 131
  Social Geography in, *review* by Prof. H. J. Fleure, 334
  Work of the Universities of (Dewar Bahadur S. E. Runganadhan), 426
India To-day, Ethical Ideals in (Dr. Edward Thompson), *review* by Dr. Mulk Raj Anand, 131
Indian Chief, Autobiography of an, *review* by Mrs. K. Rishbeth, 193
Indian Farming, 231
Indian Forest Utilization, Manual of (H. Trotter), *review* by B. J. Rendle, 167
Indian Forestry Research, 215
Indian Precious Stones (Dr. L. A. N. Iyer), 458
Indian Science Congress (Presidential Address by D. N. Wadia), 725
Indian Society, Matriliny in, *review* by Prof. J. H. Hutton, 644
Indian Timbers, Working Stresses for (V. D. Limaye), 571
Indian Woods for Battery Separators, 630
Indians (South American) of the Gran Chaco, Life among the (Sir John Graham Kerr), 555
Industrial Christian Fellowship, Growth and Activities of the (The Bishop of Bristol), 399
Industrial Electrical Instruments, Standardization of (Lieut.-Col. K. Edgcumbe), 734
Industrial Finishes, Infra-Red Baking of (H. Seymour), 371
Industrial Laboratory, Documentation in an (Miss M. Shaw), 601
Industrial Radiography (Royal Photographic Society symposium on), 519
Industrial Reconstruction: in Great Britain, 657
  Post-war (Association of British Chambers of Commerce), 33
Industrial Waters of Canada (H. A. Leverin), 264
Industries, Chemical (edited by L. Ivanovszky), sixteenth edition, *review*, 507
Industry: Encouragement of Research in (W. E. Benham), 235; (Philip R. Coursey), 374
  Entry of Youth into, 240
  The Eye in (Institute of Physics (London Branch) conference on), 80
  Government and, their Future Relations (Samuel Courtauld), 331
  Health in, 557
  Key Metals and the Location of (Prof. C. B. Fawcett), 451
  A National Policy for, 657
  Publication of Scientific Research carried out in (Dr. K. G. Denbigh), 322; (Dr. Norman R. Campbell), 408
  Research in (Foster Sproxton), 459
  (Gas) in Great Britain after the War, 95
  (Location of) on Merseyside, The Distribution of Population and the (W. Smith), 437
  (Science and), Photography in (Exhibition arranged by the Association of Scientific Workers), 519
Infant Protection in Mexico (Dr. Salvador Zubirán), 150
Infant and Maternal Mortality in relation to Size of Family and Rapidity of Breeding (Mrs. C. M. Burns), 598
Infection (Tubercular), The Golden Hamster as a Test Animal for (Dr. J. Ungar), 432
Influence of Water Vapour on Flame Gas Temperatures (Prof. W. T. David and J. Mann), 521
Infra-red Baking of Industrial Finishes (H. Seymour), 371
Inheritance: of Acquired Characters, Canalization of Development and the (Dr. C. H. Waddington), 563
  (Polyploid) in *Lythrum salicaria* (Prof. R. A. Fisher and Dr. K. Mather), 430

Inland Record of *Triglochin maritimum* L. (Frederick Burke), 405
Insect Fauna: of a Brine-Pit (Frederick Burke), 610
  of Lower California (A. E. Michelbacher and E. S. Ross), 552; (E. Gordon Linsley), 552; (E. C. Van Dyke), 552; (A. E. Michelbacher and T. H. G. Aitken), 552
Insecticidal Efficiency of some Oils of Plant Origin (A. W. Cressman and Lynn H. Dawsey), 294
Insecticides: (A Note on Derris and other Rotenone Bearing Vegetable), their Occurrence and Possibilities of Cultivation in India (T. P. Ghose), 609
  Plant Oils as, 294
  Relative Toxicity of (Dr. J. R. Busvine), 208
Insecticides and Fungicides, Committee to advise on the Official Recommendation of, 487
Insects: (Growth Factors for), Biotin, B_1, Riboflavin, Nicotinic Acid, B_6, and Pantothenic Acid as (Dr. G. Fraenkel and M. Blewett), 177
  (Integument of) and the Entry of Contact Poisons (V. B. Wigglesworth), 608
  (Relationship of) to the Spread of Azalea Flower Spot (F. F. Smith and F. Weiss), 294
  Rice Field (W. A. Douglas and J. W. Ingram), 237
Inspection (Factory) in Great Britain (Dr. T. K. Djang), *review* by R. Brightman, 390
Inspectors (Factory) and their Work, *review* by R. Brightman, 390
Instruction: (Religious) in the Schools, 559
  (Technical) for Wireless Telegraphists, Handbook of (H. M. Dowsett and L. E. Q. Walker), seventh edition, *review*, 40
Instruments, Standardization of Industrial Electrical (Lieut.-Col. K. Edgcumbe), 734
Insulation Papers (Conductor), Colour of (C. T. Wyman), 428
Insulator Glazes on Porcelain, Influence of (Dr. E. Rosenthal), 771
Insulators, Porcelain (Dr. E. Rosenthal), 19
Insurance (Social) and Allied Services (Sir William Beveridge), 753
Integument of Insects and the Entry of Contact Poisons (V. B. Wigglesworth), 608
Inter-American Friendship through the Schools (U.S. Office of Education, Bulletin No. 10, 1941), 54
Interatomic Distances in Carbon (A. Taylor), 462
International Systems and Standards (Sir Richard Gregory), 429, 620
International Table of Stable Isotopes (Dr. F. W. Aston), 515
Interrelationship of Vitamins A and E (Dr. K. C. D. Hickman, Dr. P. L. Harris and M. R. Woodside), 91
Intertidal Zonation, Causes of (Prof. T. A. Stephenson), 158
Intestinal Bacteria, Synthesis of Vitamins by (P. R. Burkholder and I. McVeigh), 553
Intravenous Glucose Tolerance Curve (G. D. Greville), 522
Introspective Psychology, *review*, 446
Intuitive Knowledge (Prof. R. I. Aaron), 770
Invertebrates (Marine), Narcotic for (Isabel C. Ledingham and G. P. Wells), 121
Ionosphere (Holes in the) and Magnetic Storms (T. L. Eckersley), 177
Ions (Hydrogen), their Determination and Importance in Pure and Industrial Chemistry (Prof. Hubert T. S. Britton), third edition, *review* by Prof. H. L. Riley, 534
Ireland (Northern), Agriculture in (J. F. Gordon), 734
Irish Loughs (some North-west), The Distribution of Phytoplankton in (W. H. Pearsall and Edna M. Lind), 28
Iron in Hæmoglobin and Hæmin, Preparation of, and Estimation of (G. E. Delory), 553
Iron Electrode Potential in a Magnetic Field (A. L. Parson), 605
Iron or Zinc (Distribution of Attack on) Partly Immersed in Chloride Solutions (Dr. Ulick R. Evans), 151
Isolation and Collection of Salivary Gland Chromosomes (J. B. Buck and A. M. Melland), 352
Iso-Magnetic Charts of the Globe (W. M. Witchell), 439; (Prof. Sydney Chapman), 439
Isotopes: International Table of Stable (Dr. F. W. Aston), 515
  (Separation of) and Thermal Diffusion (Prof. James Kendall), 136
Istanbul, University of, Dr. T. Royds appointed professor of astronomy, 317
Italy: Earthquake at Trentino on June 20, 345
  Earthquake in the Udine Province on April 12, 175

JELLY-FISH, Percentage of Water in (A. G. Lowndes), 234
Jointing (Cable), Tin Economy in (J. T. Lowe), 458
Joints, Soldering Electrical, 371
Jones-Bateman Cup of the Royal Horticultural Society, conditions of the competition for, 176
Journals (Specialist Scientific and other), Advice on the disposal of (Association of Special Libraries and Information Bureaux), 401
Junction Line Filters (F. A. Hinshaw), 159; (J. O. Israel), 159

K-1 Carrier System, A Pilot-Channel Regulator for the (J. H. Bollman), 287
Karachi, Earthquake on July 3, 54
Kelvin Lecture (thirty-third) of the Institution of Electrical Engineers (Dr. Oliver E. Buckley), 60
Kenya (Nigeria and), Results of Delayed Drying Trials in, 439
Kerguelen and the Southern Ocean, Nemerteans of (Dr. J. F. G. Wheeler), 583
Ketones, Photo-enolization of (T. Iredale), 579
Kew: Earthquake registered on July 12, 150
  Earthquake recorded on August 7, 207
  Earthquakes registered during October, 602
Key Metals and the Location of Industry (Prof. C. B. Fawcett), 451
Kidney: in Dehydration, Function of the (D. A. K. Black, Dr. R. A. McCance, and W. F. Young), 461
  (Effect of an Enzyme from) on the Solubility of Calcium Phosphate (Dr. H. Lehmann), 603
  (Rabbit), Glucose Excretion by the (Prof. T. W. T. Dillon), 492
Kilns, Timber-Seasoning (M. A. Rehman), 127
Kinematics (Engineering), (Prof. Alvin Sloane), *review*, 73
Knowledge, Intuitive (Prof. R. I. Aaron), 770
'Kryptoscreen', a New X-Ray Photographic Paper (Ilford, Ltd.), 88
Kumaun, Propagation of the Apple in (R. S. Singh), 231

LABORATORY (Industrial), Documentation in an (Miss M. Shaw), 601
Laboratory Mouse, Biology of the (The Staff of the Roscoe B. Jackson Memorial Laboratory, edited by George D. Snell), *review* by Dr. Hans Grüneberg, 101
Lactation, Non-effect of Massive Doses of Progesterone and Desoxycorticosterone on (Dr. S. J. Folley), 266
Lactation and Reproduction on Highly Purified Diets (Dr. S. J. Folley, Dr. K. M. Henry and Dr. S. K. Kon), 318
Lake Bed (Cave and) Cultures of South Central Oregon in the Northern Great Basin (L. S. Cressman), 157
Lake-dwelling or Crannog in Eadarloch, Loch Treig (Prof. James Ritchie), 639
Lake Dwellings, Scottish, 639
Lake Huleh, Palestine, Death of St. Peter's Fish in (Dr. C. K. Ricardo Bertram), 58
Lamellibranchia, The Pericardial Cavity and Pericardial Gland of the (Miss Kathleen M. White), 771
Lamellibranchs (Small Fossil), Optical Projection as an Aid in Studying Plane Spiral Coiling of (Lieut. A. T. J. Dollar), 57
Lamps (New) for Old, *review* by Rev. J. C. Hardwick, 38
Lancashire Cetacea, Records of (Eric Hardy), 492
Land Drainage, *review* by Dr. R. K. Schofield, 391
Land-Settlement—its Sanitary and Architectural Aspects and After-War Possibilities (Miss Jocelyn F. Adburgham), 571
Land Utilization: in England and Wales, 448
  in Rural Areas, Report of the Scott Committee on, 441, 448
Landscape Impression and the External Basis of Natural Beauty (L. C. W. Bonacina), 624
Lantana (The Control of) by a Sodium Chlorate Spray (A. L. Griffith), 400
Larch, A False-Ring Pattern in (Dr. C. G. Dobbs), 377
Larch-Shoot Moth, Biology of the (Bryan P. Beirne), 435
Larvæ of Decapod Crustacea (Dr. Robert Gurney), *review*, 474
Late Horizons in the Southeast (T. M. N. Lewis), 156
Latitudes (Mean Areas and Heliographic) of Sunspots during 1938 (Dr. H. Spencer Jones), 353
Lead Chromate, Structure of (S. B. Brody), 740
Lead-Calcium Test Castings (G. M. Bouton), 412
Leadership (Education and) in the Women's Services, 415
Leaf-Protein, Auxin and (S. G. Wildman and S. A. Gordon), 608
Leafhopper, The Beet (W. C. Cook), 175
League of Nations, Report for 1941–42, 354
Leaves: (Green) of Spinach Beet, A Red Colouring Matter from the (Ralph J. B. Marsden), 580; (H. G. Baker), 689
  (Tea) as a Maintenance Food for Animals (W. King Wilson), 199
Legacy, A Fateful, *review* by Prof. A. Wolf, 72; (Prof. Macgregor Skene), 150
Leningrad Botanical Institute, 487
Lenses, Electron (Dr. D. Gabor), 650
Lepidoptera: Migration of (Prof. G. D. Hale Carpenter), 526
  Studies in the Migration of (Dr. C. B. Williams, Dr. G. F. Cockbill, M. E. Gibbs and J. A. Downes), 526
Leprosy in Brazil (Eunice Weaver), 317
Lethal Effects, Ultra-violet Radiation with Special Reference to (J. R. Harris), 88
Leukæmia in Animals, Spontaneous and Experimental (Dr. Julius Engelbreth-Holm), *review* by Prof. G. R. Cameron, 133
Leverhulme Research Fellowships, awards for research, 150
Lewiston-Auburn, Maine, Earthquake of March 8, 1942 (William H. Weeks), 238
Libraries: Training in the use of (C. H. C. Osborne), 637; (Prof. R. S. Hutton), 637
  (British), Union List of Periodicals in (Theodore Besterman), 637
Library (Special) of a Research Department, Some Methods used in the (J. E. Wright), 638
Lichenin (Dr. E. G. V. Percival and H. Granichstädten), 549
Life: The Physical Basis of, *review* by Dr. I. Manton, 362
  The Problem of the Autonomy of (Prof. Reginald O. Kapp), 123; (Prof. F. G. Donnan), 123
  (Wild) in the Western Highlands (Seton Gordon), 12
  (Wild) Through the Year (Richard Morse), *review* by Seton Gordon, 506
Light: Scattering of (Dr. W. Rogie Angus), 741
  in Diamonds, Absorption and Scattering of (P. G. N. Nayar), 741
  by Liquids, Scattering of (K. S. Bai), 741
  Scattering (Fluorescence,) and the Raman Effect, Symposium on, 741
Lighting (Household), Heating and Ventilation, 231
Linear Differential Equations, *review* by Prof. L. M. Milne-Thomson, 647
Lineus corrugatus M'Intosh, Some Nemerteans from South Africa, and a Note on (Dr. J. F. G. Wheeler), 583
Lipoid Compounds in Physiological Processes, 294
Liquid Helium II, Superconductivity and (Dr. J. G. Daunt and Dr. K. Mendelssohn), 604
Liquid Structure Theory, Tensile Strength of Water and (Dr. R. S. Silver), 605
Liquids, Scattering of Light by (K. S. Bai), 741
Literature: (German Baroque), Magic and Natural Science in (Frederick Herbert Wagman), *review*, 619
  (Scientific) for Enemy Prisoners of War (Dr. John R. Baker), 408
Liver in the Salmon, Development of the (Helen I. Battle), 26
Liverpool, Post-War Reconstruction of (Alderman A. E. Shennan), 297
Liverpool (Oxford and), Reconstruction in, 297
Living Organisms, Displacement Method of Weighing (A. G. Lowndes), 695
Living World, Man's Relation to the, *review* by R. Brightman, 219
Location of Industry on Merseyside, The Distribution of Population and the (W. Smith), 437
Lockheed Ventura I., 733
Locust Plague (Dr. A. D. Imms), 742
London (Historic) under Fire (E. Yates), 242
London Gulls (T. L. Bartlett), 765
Look Forward To (Something to), a Suggestion for a New Social Contract (Lady J. Rhys Williams), 692
Loss (Artificially Induced) of Θ-Toxin Production by *Clostridium welchii* Types A and C (Dr. A. W. Turner, Catharine Eales and A. W. Rodwell), 549
Luminous Radiation from Hot Gases (Prof. W. T. David), 291
Lycopods, Carboniferous (J. M. Schopf), 26
Lythrum salicaria, Polyploid Inheritance in (Prof. R. A. Fisher and Dr. K. Mather), 430

MACHINES : (Colour of) and Workshop Efficiency, 19
  (Historic) and Apparatus, Preservation of (E. Lancaster Burne and H. W. Dickinson), 181
Mackerel, The Schooling Behavior of (Arthur Schlaifer), 663
McNair (John Calvin) lectures on the Human Meaning of Science (Arthur H. Compton), 130
Macro-molecules, Solutions of (Prof. E. K. Rideal), 602
Madras : Control of Lantana in, 399
  Teak Nurseries, Stump Production in (A. L. Griffith), 743
Magic and Natural Science in German Baroque Literature (Frederick Herbert Wagman), *review*, 619
'Magnaflux' Crack Detector (Equipment and Engineering Co., Ltd.), 344
Magnetic : Crack Detectors, 344
  Field, Iron Electrode Potential in a (A. L. Parson), 605
  Fluxmeter (E. L. Norton), 355
  Storm (Solar Eruption and) of March 1–2, 1942 (H. W. Newton), 183 ; (M. A. Ellison), 183 ; (P. Laurie), 183
  Storms, Holes in the Ionosphere and (T. L. Eckersley), 177
Magnitude (Absolute), Cyanogen Criterion of (Dorrit Hoffleit), 436
Maize Shoot, Developmental Study of the (Dr. B. C. Sharman), 435
Malaria (Prophylaxis of) in Argentina (Dr. Hugo J. D'Amato), 118
Mammalian Body (Formation of Urea in the) without Participation of Arginase (Dr. S. J. Bach and S. Williamson), 575
Mammalian Endocrine Activity, Cytological Criteria of (C. L. Foster), 279
Mammalian Hair, Histology of (Dr. J. L. Stoves), 552
Man : Fungi and the Biology of (Dr. J. Ramsbottom), 242
  and his Habitation (Prof. Radhakamal Mukerjee), *review* by Prof. H. J. Fleure, 334
Management and Morale (Prof. F. J. Roethlisberger), 669
Managerial Revolution, or What is Happening in the World Now (James Burnham), *review* by R. Brightman, 501
Manganese Deficiency, A Chlorosis of Bracken due to (James G. Hunter), 578
Manila, Destruction of the Library of the Philippines at (Colonel C. P. Romulo), 230
Man-Made Radio Interference (R. A. Shetzline), 265
Man-Power : in the National Fire Service, 354
  in Physics in the United States, 369
Man's Relation to the Living World, *review* by R. Brightman, 219
Management, Pasture, *review*, 392
Manufacture: of Fertilizer from Urban Wastes (George Bransby Williams), 299
  of Optical Glass (H. W. Lee), 214
Maps and Survey (Arthur R. Hinks), fourth edition, *review*, 675
March of Medicine, The (New York Academy of Medicine Lectures to the Laity, No. 6), *review*, 309
Marine : Annelid Worms in the United States National Museum, The Identity of some (Olga Hartman), 609
  Fauna of Bristol Channel (R. Bassindale), 435
  Invertebrates, Narcotic for (Isabel C. Ledingham and G. P. Wells), 121
Marriage and Family in Mysore (M. N. Srinivas), *review* by Mrs. S. Neville-Rolfe, 505
Marx, (Darwin,) Wagner: Critique of a Heritage (Jacques Barzun), *review* by Prof. A. Wolf, 72; (Prof. Macgregor Skene), 150
Mass Spectrometer, Portable (John A. Hipple, jun.), 111
Massachusetts, Cancer Control Programme in, 89
Materials: Strength of (Prof. S. Timoshenko), second edition, Part 1 : Elementary Theory and Problems; Part 2. Advanced Theory and Problems, *review*, 645
  for Students and Designers, *review*, 645
  (Engineering), *review* by Dr. E. H. Tripp, 195
  (Engineering), Detection of Cracks in, 343
  Handbook, an Encyclopedia for Purchasing Agents, Engineers, Executives and Foremen (George S. Brady), fourth edition, *review* by Dr. E. H. Tripp, 195
Maternal Mortality (Infant and) in relation to Size of Family and Rapidity of Breeding (Mrs. C. M. Burns), 598
Mathematical: Gymnastics with Calculating Machines (Dr. L. J. Comrie), 427, 527
  Statistics, The Fundamental Principles of (Hugh H. Wolfenden), *review* by Prof. R. A. Fisher, 196
  Tables, Errors in (Dr. L. J. Comrie), 738
Mathematics: (Applied), Operational Methods in (Prof. H. S. Carslaw and J. C. Jaeger), *review* by Prof. L. M. Milne-Thomson, 647
  The Content of, *review* by Prof. G. H. Hardy, 673
  Elementary (Prof. Hyman Levy), *review* by F. G. W. Brown, 507
  What is (Richard Courant and Herbert Robbins), *review* by Prof. G. H. Hardy, 673
  in the U.S.S.R. (Prof. Ivan Vinogradov), 677
Mating: in *Euplotes partella*, Genetics of (R. F. Kimball), 295
  Call-note of Moths (N. L. Silvester), 463
  Swarm in a Chironomid, *Spaniotoma minima* (Dr. N. H. E. Gibson), 268
Matriliny in Indian Society, *review* by Prof. J. H. Hutton, 644
Measurement: of Electronic Charge (Prof. T. H. Laby), 648
  of Trees (Reginald Davey), *review*, 333
Measurements: (Gravity) in Guatemala (F. E. Wright), 352
  High-Pressure (P. W. Bridgman), 183
Mechanics: of Earthquakes where there is no Surface Faulting (L. Don Leet), 300
  (Engineering) (Prof. S. Timoshenko and Prof. D. H. Young), second edition, *review*, 73
Mechanism: of Metallic Friction (Dr. F. P. Bowden and D. Tabor), 197; (Dr. J. E. Hurst), 349
  of Sensitivity Changes of Sense Organs (Prof. Krikor Kekcheev), 491; (Dr. G. W. Scott Blair and F. M. V. Coppen), 580
  (Muscle), A Theory of (Walter Goldstern), 572
Mechanisms: (Calculating Machine), A Description of (R. S. Nilsson), 427, 527
  Visual (edited by Prof, Heinrich Kluver), *review* by Prof. E. D. Adrian, 727
Medal Awards of the Royal Society, 571, 665
Medical Miscellany (Schuman's), List E, 90; List F, 631
Medical Practice (Native) in Africa, *review*, 36
Medical Relief in Europe (Dr. M. D. Mackenzie), 288
Medical Research, The Furtherance of (Dr. Alan Gregg), *review*, 619
Medical Services of the Sudan, Report of the Director for 1940, 631
Medicine: Advances in, *review*, 309
  (Historical) and Science, Books on, 631
  The March of (New York Academy of Medicine Lectures to the Laity, No. 6), *review*, 309
  Montesquieu and (Dr. Camille Dreyfus), 231
  Native African, with Special Reference to its Practice in the Mano Tribe of Liberia (Dr. George Way Harley), *review*, 36
  Social, 129
  (Social) at Oxford, 116
  (Tropical) at Havana, Institute of, 488
  (Tropical), A History of (Sir H. Harold Scott), second impression, *review*, 507
Melchett Lecture on the Analysis and Testing of Coal in relation to its Properties and Utilization (Dr. Arno Carl Fieldner), 372, 667
Melchett Medal of the Institute of Fuel for 1942 to be presented to Dr. Arno Carl Fieldner, 372
Membrane (Cell), Potassium, Fermentation and the (Prof. Edward J. Conway), 461
Men (Scientific) in War-Time, 65
Mendeléeff-Brauner Tradition in Czech Chemistry (Dr. Gerald Druce), 623
Mercury-Arc Mutators (Grid-Controlled), Static Conversion of Direct Current to Alternating Current with (R. Feinberg), 664
Merseyside, The Distribution of Population and the Location of Industry on (W. Smith), 437
Metabolic Water and Desiccation (Dr. Kenneth Mellanby), 21
Metabolism (Sugar), Influence of Potassium on (Dr. S. N. Farmer and D. A. Jones), 768
Metal Crystals, Elastic Constants of (K. Fuchs and H. W. Peng), 436
Metal Points (Single Crystal), Autoelectronic Emission from (M. Benjamin and R. O. Jenkins), 295
Metal Rectifier and the Carborundum Ceramic Non-Linear Resistor, Contact Non-Linearity with reference to the (A. Fairweather), 743
Metal Tubes of Rectangular Cross-section, Electromagnetic Waves in (J. Kemp), 32
Metallic Friction, Mechanism of (Dr. F. P. Bowden and D. Tabor), 197; (Dr. J. E. Hurst), 349
Metals: from Scrap, Recovery of (Sir Harold Hartley), 594
  (Bearing), Frictional Properties of (J. L. Heaton, J. R. Bristow, G. Whittingham and Dr. T. P. Hughes), 520
  (Key) and the Location of Industry (Prof. C. B. Fawcett), 451
  (New) and New Methods (Dr. C. H. Desch), 419
Meteorites, Origin of, 175
Meteoritics, Trends in (H. H. Mininger), 175
Methacrylate (Catalysed Polymerization of Methyl) in the Liquid Phase (Prof. R. G. W. Norrish and R. R. Smith), 336
Method (Displacement) of Weighing Living Organisms (A. G. Lowndes), 695
Methods: (New), New Metals and (Dr. C. H. Desch), 419
  (Operational) in Applied Mathematics (Prof. H. S. Carslaw and J. C. Jaeger), *review* by Prof. L. M. Milne-Thomson, 647
Methyl Methacrylate (Catalysed Polymerization of) in the Liquid Phase (Prof. R. G. W. Norrish and R. R. Smith), 336
Mexican National Astrophysical Observatory at Tonanzintla, dedication marked by the issue of postage stamps, 229
Mexico: General Health and Dental Hygiene in (Dr. Miguel E. Bustamante), 401
  Infant Protection in (Dr. Salvador Zubirán), 150
  (Central America and), Archæological Work of the Carnegie Institution in (Dr. Sylvanus G. Morley), 155
Michelia Timbers for Aircraft, 630
Micro-determination of Calcium in Serum (P. F. Holt and H. J. Callow), 553
Micro-organisms (the Growth of) in Presence and Absence of *p*-Aminobenzoic Acid, Effect of Sulphanilamides on (Sten Wiedling), 290
Microbial Factors in the Digestive Assimilation of Starch and Cellulose in Herbivora (Frank Baker), 479
Microfilm, Documentation and, 601
Microfilming Processes, Apparatus for use with (B. K. Johnson), 601; (E. H. Lindgren), 601
Microfilms (Mrs. Lucia Moholy), 637; (E. Lancaster-Jones), 637; (Dr. Vernon Tate), 637
Middle East (Europe and), Map of (British Council), 543
Migration: of Lepidoptera (Prof. G. D. Hale Carpenter), 526
  of Lepidoptera, Studies in the (Dr. C. B. Williams, Dr. G. F. Cockbill, M. E. Gibbs and J. A. Downes), 526
Milestones of Communication Progress (H. T. Kohlhaas), 63
Military Service, University Students and, 732
Milk: The Pasteurization of (Prof. G. S. Wilson), *review* by Prof. H. D. Kay, 587
  (Cow's), Copper-bearing Protein in (W. L. Dills and J. M. Nelson), 524 609
Milk Industry, Future of the (Prof. H. D. Kay), 41
Milky Way, Structure and Rotation of the, 169
Milroy Lectures for 1942, 345
Mineral Oils, Cancer-producing (R. Lyth), 765
Mineral Resources: of the U.S.S.R. (Dr. David Williams), 539
  and the Atlantic Charter (British Association, Division for the Social and International Relations of Science, conference on), 171, 201
  (Relation of) to World Peace (Sir Thomas Holland), 364
  (World), a Suggested Survey (Prof. P. G. H. Boswell), 565
Mineral and Vitamin Requirements and the War-time Dietary (Prof. R. A. Peters), 125
Minerals: (Exploitation of) in relation to National and World Planning (Dr. L. Dudley Stamp), 395
  Old and New, from the Sea (Dr. E. F. Armstrong), 453
Mining, Opencast (Prof. J. A. S. Ritson), 44
Moisture in Living Tissue, Estimation of (E. G. Hallsworth and R. L. Reid),
Moisture Content, Determination of (Dr. L. G. G. Warne), 607
Molecule (Selenanthren), Folding of the (Raymond G. Wood and Gordon Williams), 321
Molecules (Macro-), Solutions of (Prof. E. K. Rideal), 602
Monocotyledon (Dicotyledon and), Shoot Organization in, 95
Montesquieu and Medicine (Dr. Camille Dreyfus), 231
Montevideo, Institute of Endocrinology at, 207
Monuments (Historic) in the U.S.S.R., Restoration of, 54
Moon: Illusions about the Size of the (Prof. E. G. Boring), 629
  (Effect of the) on Germination and Seedling Growth (M. Mather), 630
Morale: (Dr. Joseph Geoghegan), 9
  Management and (Prof. F. J. Roethlisberger), 669
  Relation of Co-operation to, 669
Morris (Malcolm) Memorial Chadwick Lecture on Tuberculosis in Peace and War (Sir Arthur MacNalty), 676

Mortality: Cancer, 631
  (Infant and Maternal) in relation to Size of Family and Rapidity of Breeding (Mrs. C. M. Burns), 598
Moscow: Darwinian Exhibition in (Sir Arthur Keith), 393
  Scientific Exhibition in, 369
Mosotti (Clausius-) Formula, Validity of the (Dr. G. Burniston Brown), 661
Mosquitoes, Salivary Gland Chromosomes in (Eileen Sutton), 553
Moth (Larch-Shoot), Biology of the (Bryan P. Beirne), 435
Mother-right in India (Baron Omar Rolf Ehrenfels), *review* by Prof. J. H. Hutton, 644
Moths, Mating Call-Note of (N. L. Silvester), 463
Motion: Photographic Analysis of (E. R. Davies), 765
  of the Sun in the Galaxy (Ralf E. Wilson), 400
Motor Vehicles and their Engines (Norman G. Shidle and Thomas A. Bissell), fifth edition, *review*, 74
Motors (Electric), Overheating of, 287
Mountbatten Medal of the British Institution of Radio Engineers, 150
Mouse: Biology of the Laboratory (The Staff of the Roscoe B. Jackson Memorial Laboratory, edited by George D. Snell), *review* by Dr. Hans Grüneberg, 101
  Cytoplasmic Inclusions in the Germ Cells of the (Dr. R. A. R. Gresson), 663
Mouth (Frog's), Demonstration of Action of Ciliated Epithelium of the (G. B. West), 580
Mouth-Parts of a Weevil, *Calandra granaria* (Dr. R. Dennell), 552
Movement (Biological), Nomenclature of (Cyril Bibby), 405
Mucorine Parasite on Penicillia (Dr. C. G. Dobbs), 319
Municipal Services (Civil and), Reconstruction in the (G. D. H. Cole), 331
Mürtschenstock, Earthquake on June 25, 345
Muscle Contraction (is) essentially an Enzyme-Substrate Combination ? (Dr. Joseph Needham, Dr. Arnošt Kleinzeller, Miss Margaret Miall, Mrs. Mary Dainty, Dr. Dorothy M. Needham and Dr. A. S. C. Lawrence), 46
Muscle Mechanism, A Theory of (Walter Goldstern), 572
Museums and Art Galleries, Yorkshire Federation of, T. Sheppard elected an honorary life member, 119
Musical Notation: Simplification of (Lieut. Alan G. Smalley), 211; (Kenneth B. Wood), 322; (W. E. Ingerson), 322
  Simplification of, 317
Mutators (Grid-Controlled Mercury-Arc), Static Conversion of Direct Current to Alternating Current with (R. Feinberg), 664
Mycological Taxonomy, 609
Mysore, Marriage and Family in (M. N. Srinivas), *review* by Mrs. S. Neville-Rolfe, 505

NAPHTHALENE, Raman Effect in a Single Crystal of (T. M. K. Nedungadi), 741
Narcotic for Marine Invertebrates (Isabel C. Ledingham and G. P. Wells), 121
Nation ? What Constitutes a (J. R. Swanton), 286
National Expenditure: Eleventh Report of the Select Committee on, 329
  Thirteenth Report of the Select Committee on, 354
  Fifteenth Report of the Select Committee on, 611
  Sixteenth Report of the Select Committee on, 733
  Seventeenth Report of the Select Committee on, 693
  Eighteenth Report of the Select Committee on, 641
National Fire Service, Man-Power in the, 354
National Flour and Bread, Second Report on, 538
National Policy for Industry, 657
National Trust, forty-seventh annual report, 287
National and World Planning, The Exploitation of Minerals in relation to (Dr. L. Dudley Stamp), 395
Nations: The League of, Report for 1941-42, 354
  The Teacher of (edited by Dr. Joseph Needham), 602
Native African Medicine, with Special Reference to its Practice in the Mano Tribe of Liberia (Dr. George Way Harley), *review*, 36
Native Proteins, Flexible Frameworks and Cytoplasmic Organization (Dr. Dorothy Wrinch), 270
Natural Beauty, Landscape Impression and the External Basis of (L. C. W. Bonacina), 624
Natural Population, Genetics of (C. Epling and T. H. Dobzhansky), 237
Natural Science (Magic and) in German Baroque Literature (Frederick Herbert Wagman), *review*, 619
Naturalists, British and Russian, 117
Nature Reserves Investigation Committee, 230
Nature Diary, A, *review* by Seton Gordon, 506
Navigation (Astro-), The Observer's Book on (Flight.-Lieut. Francis Chichester), Part 4, *review*, 8
Nazca, Earthquake on August 24, 288
Nematode Parasites of the Horse (Dr. W. A. Rosa and Dr. E. J. Galofre), 663
Nemerteans: Notes on Bermudan, *Gorgonorhynchus bermudensis* n.sp. (Dr. J. F. G. Wheeler), 583
  of Kerguelen and the Southern Ocean (Dr. J. F. G. Wheeler), 583
  from South Africa and a Note on *Lineus corrugatus* M'Intosh (Dr. J. F. G. Wheeler), 583
Neoplasm (A Cancerous) of Plants (Philip R. White), 237
Nettle (Common Stinging), Economic Value of the (Dr. C. R. Metcalfe), 83
Neuenburgersee, Earthquake on March 15, 175
Neurohumour (Colour) in Sharks, Selachine as a (G. H. Parker), 182
New (The Old and the) in India, *review* by Dr. Mulk Raj Anand, 131
New Guinea, Earthquake on June 6, 459
New Hampshire Earthquakes of 1940, Cause of the, 300
New Metals and New Methods (Dr. C. H. Desch), 419
New Order, Education in the (Miss Knight-Bruce), 399
New York Academy of Medicine Lectures to the Laity, No. 6: The March of Medicine, *review*, 309
New Zealand: Earthquake on June 24, 18; Earthquakes registered during March, 18; Earthquakes during April, and on June 14, 119; Earthquakes registered during June, 459; Earthquakes during August, 659
  Earthquake Activity in, 243
  Earthquakes in (Dr. J. Henderson and R. C. Hayes), 554
  Seismicity of (R. C. Hayes), 243
Newspaper (American) Reporting of Science News (Hillier Krieghbaum), 174
Newton: Sir Isaac, the Pioneer of Astrophysics (Elizabeth Connor), 149
  as an Experimenter (Lord Rayleigh), 628, 655, 706
  and the Science of his Age (Prof. E. N. da C. Andrade), 628, 655, 700
  and the Science of To-day (Sir James Jeans), 628, 655, 710
  Scientist and Man (Prof. S. Brodetsky), 698
  Tercentenary Meetings, 628
  Tercentenary, Royal Society celebrations, 654
  (Galileo,) and Halley, 483
Newton's Books, Exhibition of, 658
Newton's Life and Works, 731
Newton's Work, Some Historical Aspects of (Dr. H. Buckley), 731
$Ni(NO_3)_2.6NH_3$, Formation of a Double Crystal Aggregate and the Structure of the Intermediate Temperature Modification of (S. H. Yü), 347
Nicaragua (south of the Golfo de Fonseca), Earthquake on September 26, 687
Nicotinic Acid (Biotin, B_1, Riboflavin), B_6 and Pantothenic Acid as Growth Factors for Insects (Dr. G. Fraenkel and M. Blewett), 177
Nigeria and Kenya, Results of Delayed Drying Trials in, 439
Nigerian Kingdom, A, *review* by Dr. C. K. Meek, 749
Nitrogen, Active (Lord Rayleigh), 238
Noise (Planning against), Practical Acoustics and (Hope Bagenal), *review* by N. Fleming, 193
Nomenclature: of Biological Movement (Cyril Bibby), 405
  (Classification and) of Cancer (Dr. C. Zuckermann), 573
Non-ionizing (Penetrating) Component of Cosmic Radiation and Penetrating Showers, Connexion between the (Dr. L. Jánossy and Dr. G. D. Rochester), 633
Non-Linearity (Contact) with reference to the Metal Rectifier and the Carborundum Ceramic Non-Linear Resistor (A. Fairweather), 743
North Sea, Phytoplankton of the, 1938–39, Part 2: Dinoflagellates, Phæocystis, etc. (C. E. Lucas); The Faeroe-Shetland Channel, 1939 (C. E. Lucas, N. B. Marshall and C. B. Rees), 555
Notatin, an Anti-bacterial Glucose-aerodehydrogenase from *Penicillium notatum* Westling (C. E. Coulthard, Dr. R. Michaelis, Dr. W. F. Short, G. Sykes, G. E. H. Skrimshire, A. F. B. Standfast, Dr. J. H. Birkinshaw and Dr. H. Raistrick), 634
Notation (Musical): Simplification of (Lieut. Alan G. Smalley), 211; (Kenneth B. Wood), 322; (W. E. Ingerson), 322
  Simplification of, 317
Nova, Discovery of a, 601
Nova Cygni (1942) (George Alter), 463
Nucleotides (Role of Adenine) and Growth Factors in Increased Proliferation following Damage to Cells (Prof. John R. Loofbourow), 349
Nutrition and Size of Family, Report on a New Housing Estate, 1939 (Prepared for the Birmingham Social Survey Committee by M. S. Soutar, Dr. E. H. Wilkins and Dr. P. Sargant Florence), *review*, 475
Nutritional Research, 413
Nutritive Value of Meals in 'British Restaurants', 51

OBSERVATIONS (Spectrographic) at the Total Eclipse of October 1, 1940 (R. O. Redman), 353
Observer's Book on Astro-Navigation (Flight-Lieut. Francis Chichester), Part 4, *review*, 8
Œstrogen (A New Synthetic) with Prolonged Action when Given Orally (Dr. J. M. Robson, A. Schönberg and Dr. Wadie Tadros), 22, 429
Œstrogens (Synthetic), 'Ghost' Formation in Subcutaneously Implanted Tablets of (Dr. S. J. Folley), 403
Oil-bearing Plants in Sweden, 176
Oils: (Mineral), Cancer-producing (R. Lyth), 765
  (Plant) as Insecticides, 294
  of Plant Origin, Insecticidal Efficiency of some (A. W. Cressman and Lynn H. Dawsey), 294
Old and the New in India, *review* by Dr. Mulk Raj Anand, 131
Old Testament Sources, North Syrian Archæology and (M. C. Burkitt), 327
Onions and Vernalization (Jean Margaret Fry), 689
Opencast Mining (Prof. J. A. S. Ritson), 44
Open-Hearth Furnace Refractories (Iron and Steel Institute and the Society of Engineers and Metallurgists discussion on), 184
Operational Methods in Applied Mathematics (Prof. H. S. Carslaw and J. C. Jaeger), *review* by Prof. L. M. Milne-Thomson, 647
Ophthalmic Folk-lore (Dr. J. D. Rolleston), 573
Opium and other Dangerous Drugs, Control of, 370
Opium Board (Permanent Central), forty-first session, 370
Optical Glass, Manufacture of (H. W. Lee), 214
Optical Projection as an Aid in Studying Plane Spiral Coiling of Small Fossil Lamellibranchs (Lieut. A. T. J. Dollar), 57
Optical Reflections from Coal (C. G. Cannon and Dr. W. H. George), 690
Optics Applied to Engineering (K. J. Habell), 53
Optional-control System of Domestic Electricity Supply (P. Schiller), 53
Orchid, A New British, *Epipactis pendula* (C. Thomas), 88
Organisms (Living), Displacement Method of Weighing (A. G. Lowndes), 695
Organization, Science and (Prof. A. E. Trueman), 434
Organs: (Homology of the Campaniform) on the Wing of *Drosophila melanogaster* (Dr. A. D. Lees), 375
  (Sense), Mechanism of Sensitivity Changes of (Prof. Krikor Kekcheev), 491; (Dr. G. W. Scott Blair and F. M. V. Coppen), 580
Oregon (South Central) in the Northern Great Basin, Cave and Lake Bed Cultures of (L. S. Cressman), 157
Organization: of Post-War Relief in Europe, 305
  of Science for War, 301
Organization (Shoot): in Dicotyledon and Monocotyledon, 95
  of *Heraclium sphondylium* (C. P. Majumdar), 95
Origin: of the Coronium Lines (Dr. A. Hunter), 756
  of Tetraploid Shoots in *Brassica oleracea* (H. W. Howard), 739
Osborn, Henry Fairfield, and the American Museum of Natural History (Prof. W. K. Gregory), 513
Oscillator Scales, Automatic Production of (T. Slonczewski), 438
Osler (Sir William): The Life of (Harvey Cushing), *review*, 675
  Medal of the American Society of the History of Medicine awarded to John T. Barrett, 573
Otology and Folklore (Dr. J. D. Rolleston), 496
Outlines of Entomology (Dr. A. D. Imms), *review* by Dr. V. B. Wigglesworth, 505
Overheating of Electric Motors, 287

Oxazoline and Thiazoline Rings in Proteins (S. Blackburn, W. R. Middlebrook and H. Phillips), 57
Oxford: Preservation of, 273
  Social Medicine at, 116
Oxford and Liverpool, Reconstruction in, 297
Oxidation by Copper in Alcoholic Medium (Dr. E. M. Mystkowski), 234
Oxidation Products of Pressor Amines, Antipressor and Depressor Effects of (Dr. Kurt A. Oster), 289
Oxyhæmoglobin, Crystal Structure of (M. F. Perutz), 324
Oysters in Australia, Biology and Cultivation of (G. Humphreys), 544

PACIFIC: (North) Polychæta, chiefly from the West Coast of Vancouver Island, Alaska and Bering Sea (E. and C. Berkeley), 609
  (Tropical), Foraminifera of the (J. A. Cushman), 182
Pacific Ocean: Earthquake off Tumaco, Colombia, on May 14, 118
  Earthquake on July 8, 345
  (between Kamchatka and the Aleutian Islands), Earthquakes on August 23, September 2, 4 and 9, 632
  (off Central America), Earthquakes on August 6 and September 4, 632
Pacific Relations in the Post-War World, 495
Pantothenic Acid (Biotin, B_1, Riboflavin, Nicotinic Acid, B_6 and) as Growth Factors for Insects (Dr. G. Fraenkel and M. Blewett), 177
Paper (A Recording) for Field and General Use (A. G. Tarrant), 153
Paper and Board, Bagasse for the Manufacture of (M. P. Bhargava and A. N. Nayer), 88
Papers, Colour of Conductor Insulation (C. T. Wyman), 428
Paracelsus and "Basil Valentine" (Prof. F. A. Paneth), 380; (Dr. W. H. S. Jones), 380
Parasite (A Mucorine) on Penicillia (Dr. C. G. Dobbs), 319
Parasites: of the Shisham Defoliators in the Punjab Plantations, On the Biology of the (R. N. Mathur and C. F. C. Beeson), 552
  (Animal), Immunity against (Prof. James T. Culbertson), *review* by Lieut.-Colonel F. Murgatroyd, 360
  (Nematode) of the Horse (Dr. W. A. Rosa and Dr. E. J. Galofre), 663
Parents Revolt, a Study of the Declining Birth-rate in Acquisitive Societies (Richard and Kathleen Titmuss), *review*, 646
Parsley as a Rich Source of Vitamin C (E. J. Morgan), 92
Parsons Memorial Lecture of the Institute of Marine Engineers, to be delivered by Dr. S. F. Dorey, 232
Parsons, William (Experiments of) for the Improvement of Reflecting Telescopes (M. A. Ellison), 458
Part-time Employment (F. C. Hooper), 17
Parthenocarpy Induced by Frost in Pears (D. Lewis), 608
Partnership (Colonial Development, the Progress to), 161
Pascal: the Inventor of the first Calculating Machine (Prof. S. Chapman), 427, 527; (Prof. René Cassin), 427, 527
  Blaise (1623–1662), Tercentenary of the Calculating Machine (Prof. S. Chapman), 508
  Tercentenary Celebration, 527
Pasteurization of Milk (Prof. G. S. Wilson), *review* by Prof. H. D. Kay, 587
Pasture Management, *review*, 392
Patterson Function, A Modified (Dr. Chia-Si Lu), 407
Pays d'Enhaut, Earthquake on July 1, 545
Peace: The Discipline of (K. E. Barlow), *review* by R. Brightman, 219
  War and the Psychological Conditions of (Dr. William Brown), *review*, 590
  (War and), National Exhibition of Soviet Life in, 519
  (War and), Psychology of, *review*, 590
  and War, Science in (Watson Davis), 310
  and War, Tuberculosis in (Sir Arthur MacNalty), 676
  (World), Relation of Mineral Resources to (Sir Thomas Holland), 364
Peace-time Health, War-time Lessons for, 518
Peach, Bacterial Canker of the (H. Wormald), 295
Peak-Factor Meter, An A.C. and D.C. (E. H. W. Banner), 401
Pears, Parthenocarpy Induced by Frost in (D. Lewis), 608
Pedagogy (Engineering), *review*, 73
Pedler Lecture of the Chemical Society (Dr. W. H. Mills), 572
Penetrating Showers, Connexion between the Penetrating Non-ionizing Component of Cosmic Radiation and (Dr. L. Jánossy and Dr. G. D. Rochester), 633
Penicillia, A Mucorine Parasite on (Dr. C. G. Dobbs), 319
Penicillin: Production of (Dr. S. W. Challinor), 688
  Purification and Chemistry of (Dr. J. R. Catch, Dr. A. H. Cook and Prof. I. M. Heilbron), 633
Penicillium notatum Westling, Notatin, an Anti-bacterial Glucose-aerodehydrogenase from (C. E. Coulthard, Dr. R. Michaelis, Dr. W. F. Short, G. Sykes, G. E. H. Skrimshire, A. F. B. Standfast, Dr. J. H. Birkinshaw and Dr. H. Raistrick), 634
Pericardial Cavity and Pericardial Gland of the Lamellibranchia (Miss Kathleen M. White), 771
Periodicals: in British Libraries, Union List of (Theodore Besterman), 637
  The Subject Index to, 1940, *review*, 8
  War-time Books and (B. M. Headicar), 638
Personal Factor in Accidents (Industrial Health Research Board, Emergency Report No. 3), 396
Personality, Foundations for a Science of (Dr. Andras Angyal), *review* by J. Drever, 418
Personnel (Problems of) in Public Services, 357
Peru: Earthquake on August 24, 288, 345, 632
  Public Health in (Dr. Constantino J. Carvallo), 371
Petroleum, Derivation of, *review*, 194
  Source Beds of (Parker D. Trask and H. Whitman Patnode), *review*, 194
Phallostethids, New and Little-known (Albert W. C. T. Herre), 639
Philippines: Destruction of the Library at Manila (Colonel C. P. Romulo), 230
  University of the, 20
Philosophical Magazine, Philosophy in the, 89
Philosophy: of Edmund Husserl (E. Parl Welch), *review*, 222
  in the *Philosophical Magazine*, 89
  of the Physical Sciences, Some Disputed Questions in the (Prof. E. T. Whittaker), 89
  of the Universe, *review* by Prof. A. D. Ritchie, 69
Photo-enolization of Ketones (T. Iredale), 579
Photographic Analysis of Motion (E. R. Davies), 765
Photographic Identification of Timbers, *review* by Dr. C. R. Metcalfe, 533
Photographic Paper, A New X-Ray (Ilford, Ltd.), 88
Photographic Process, Recent Advances in our Knowledge of the (Dr. C. E. Kenneth Mees), 720
Photography in Science and Industry (Exhibition arranged by the Association of Scientific Workers), 519
Photography's Part in the War (Exhibition arranged by Kodak, Ltd.), 519
Photometry (Stellar), Rotating Sectors in (Donald A. MacRae), 436; (L. F. Barcus), 436
Physical Basis of Life, *review* by Dr. I. Manton, 362
Physical Sciences, Some Disputed Questions in the Philosophy of the (Prof. E. T. Whittaker), 89
Physicist, The Making of a, 245
Physicists: After the War (Sir Lawrence Bragg), 75, 373
  Education and Training of (Institute of Physics discussion on), 429, 568; (J. A. Crowther), 568
Physics: Reports on Progress in, Vol. 8 (1941), *review* by Prof. J. A. Crowther, 71
  Some Aspects of, *review* by Prof. J. A. Crowther, 71
  Scientific Films and their Use in the Teaching of (Physical Society discussion on), 691
  in Biology, *review* by Dr. Harold Jeffreys, 332
  Bibliography, 90
  to the Heating and Ventilation of Buildings, Applications of (A. F. Dufton), 678
  (Atomic), Introduction to (Dr. S. Tolansky), *review* by Prof. A. M. Tyndall, 308
  (Man-Power in) in the United States, 369
  and Chemistry of Surfaces (Prof. Neil Kensington Adam), third edition, *review* by Prof. Eric K. Rideal, 730
Physiography of the Southern Counties of England, Constructional Elements in the (F. Owen Whitaker), 242
Physiological Assay of Pyrethrum Extracts, A Method of (Dr. Otto Lowenstein), 760
Physiological Processes, Lipoid Compounds in, 294
Physiology: Annual Review of (James Murray Luck, editor; Victor E. Hall, associate editor), Vol. 4, *review* by Prof. C. Lovatt Evans, 276
  of Vision, *review* by Dr. Katharine Tansley, 166
  (Cell), Cytology and (edited by Geoffrey Bourne), *review* by Dr. I. Manton, 362
Phytoplankton: of the North Sea, 1938–39, Part 2: Dinoflagellates, Phæocystis, etc. (C. E. Lucas); The Færoe-Shetland Channel, 1939 (C. E. Lucas, N. B. Marshall and C. B. Rees), 555
  in some North-west Irish Loughs, The Distribution of (W. H. Pearsall and Edna M. Lind), 28
Pigeon (Wood-) Investigation, 544
Pilot-Channel Regulator for the K-1 Carrier System (J. H. Bollman), 287
Plan, The Beveridge Security, 753

Population: of Great Britain, Future of the (Colonel Sir Charles Arden-Close), 140
  (Distribution of) and the Location of Industry on Merseyside (W. Smith), 437
  (Natural), Genetics of (C. Epling and T. H. Dobzhansky), 237.

Population Statistics, The New (Dr. R. R. Kuczynski), 487
Porcelain, Influence of Insulator Glazes on (E. Rosenthal), 771
Porcelain Insulators (Dr. E. Rosenthal), 19
Post-War Economy, General Principles of a (London Chamber of Commerce), 33
Post-War Education and Training of Physicists (Institute of Physics discussion on), 568
Post-War Industrial Reconstruction (Association of British Chambers of Commerce), 33
Post-War Medical Relief, 288
Post-War Period, Electrical Engineers and the (Prof. C. L. Fortescue), 467
Post-War Planning in the United States, 457
Post-War Reconstruction: of Agriculture in Europe, appointment of a British Association Committee to collaborate with the Allied Technical Advisory Committee on, 346
  of Liverpool (Alderman A. E. Shennan), 297
Post-War Relief in Europe, Organization of, 305
Post-War World, Pacific Relations in the, 495
Potassium: in Bacterial Fermentation (Dr. J. Leibowitz and N. Kupermintz), 233
  Fermentation and the Cell Membrane (Prof. Edward J. Conway), 461
  on Sugar Metabolism, Influence of (Dr. S. N. Farmer and D. A. Jones), 768
Potato: Food Value of the, 518
  Disinfection (Seed) by Conveyor Belt Dipper (C. T. N. Wakely and H. C. Mellor), 769
  Species (Certain Diploid), Self-incompatibility in (G. P. Carson and H. W. Howard), 290
  Virus Diseases (F. C. Bawden), 476
Potatoes, Soviet Scientific Work on (Prof. A. T. Lysenko), 456
Potential (Iron Electrode) in a Magnetic Field (A. L. Parson), 605
Pouch in the Male of *Trichosurus vulpecula*, Experimental Production of a (Dr. A. Bolliger), 688
Power Stations, Siting of (F. Favell), 53
Precession, Calculation of (D. H. Sadler), 740
Precious Stones, Indian (Dr. L. A. N. Iyer), 458
Precolombian Haiti, *review* by G. H. S. Bushnell, 103
Preservation: of Historic Machines and Apparatus (E. Lancaster Burne and H. W. Dickinson), 181
  of Oxford, 273
  of Plant Material (Dr. L. G. G. Warne), 661
Presse Griechenland, Earthquake on June 1, 345
Pressor Amines, Antipressor and Depressor Effects of Oxidation Products of (Dr. Kurt A. Oster), 289
Primatologica (Bibliographia), Part I: Anatomy, Embryology and Quantitative Morphology; Physiology, Pharmacology and Psychobiology; Primate Phylogeny and Miscellanea (Theodore C. Ruch), *review*, 74
Primes (Number of) and Probability Considerations (Prof. W. H. Furry), 120; (Lord Cherwell), 120
Prisoners (Enemy) of War, Scientific Literature for (Dr. John R. Baker), 408
Private Schools in America (Willard Connely), 434
Probability Considerations, Number of Primes and (Prof. W. H. Furry), 120; (Lord Cherwell), 120
Problem in Econometrics, A, *review* by Dr. A. L. Bowley, 335
Problems: of the *A*-Type Stars (Otto Struve and P. Swings), 370
  of Personnel in Public Services, 357
Production: Consumption and Distribution, World Co-operation in, 387
  The Human Factor in (Dr. May Smith), 142
  Statistical ('Quality') Control of (Sir Charles Darwin), 117
  (Automatic) of Oscillator Scales (T. Slonczewski), 438
  (Electrical) of Bullet-proof Steel (A. G. Arend), 298
Production Committees, Sociological Aspects of, 1
Profession, Politics as a, *review* by Dr. Joseph Geoghegan, 472
Progesterone and Desoxycorticosterone (Non-Effect of Massive Doses of), on Lactation (Dr. S. J. Folley), 266
Progress: Milestones of Communication (H. T. Kohlhaas), 63
  to Partnership (Colonial Development, the), 161
  in Physics, Reports on, Vol. 8 (1941), *review* by Prof. J. A. Crowther, 71
Proliferation (Increased) following Damage to Cells, Role of Adenine Nucleotides and Growth Factors in (Prof. John R. Loofbourow), 349
'Promin', Experimental Studies with (Prof. W. H. Tytler), 517
Properties: (Electrical) of Polystyrene (F. T. Farmer), 521
  (Frictional) of Bearing Metals (J. L. Heaton, J. R. Bristow, G. Whittingham and Dr. T. P. Hughes), 520
Prophylaxis of Malaria in Argentina (Dr. Hugo J. D'Amato), 118
Projection (Optical) as an Aid in Studying Plane Spiral Coiling of Small Fossil Lamellibranchs (Lieut. A. T. J. Dollar), 57
Proliferation-promoting Activities of Extracts from Ultra-Violet Injured Yeast Cells and of Bios Components (Prof. Elton S. Cook and Sister Ann Gertrude Cronin), 93
Protein: (Copper-bearing) in Cow's Milk (W. L. Dills and J. M. Nelson), 609
  (Leaf-), Auxin and (S. G. Wildman and S. A. Gordon), 608
Proteins: (Native), Flexible Frameworks and Cytoplasmic Organization (Dr. Dorothy Wrinch), 270
  Oxazoline and Thiazoline Rings in (M. Blackburn, W. R. Middlebrook and H. Phillips), 57
  (Structure of), Amino Acid Analysis and the (Prof. A. C. Chibnall), 127
Protozoa in the Activated Sludge Process, Role of (S. C. Pillai and Prof. V. Subrahmanyan), 525; (Dr. S. H. Jenkins), 607
Prunus Hybrids, Artificial Culture of (G. W. Skimm), 435
Psychiatry and Alcoholism (Dr. Merrill Moore), 400
Psychological Aspects of English Social Stratification (Prof. T. H. Pear), 465
Psychological Conditions of Peace, War and the (Dr. William Brown), *review*, 590
Psychological Study of Twins, *review*, 195
Psychologist: and its Effect upon his Work, The Social Status of the (Prof. T. H. Pear), 741
Psychology: of War and Peace, *review*, 590
  (Animal), The Discrimination Method in (Dr. H. Honigmann), 29
  Child, *review* by A. W. Wolters, 749
  (Experimental), Medical Research Council studentship for training in methods of, 346
  Introspective, *review*, 446
  and Religious Truth (Dr. Thomas Hywel Hughes), *review* by Rev. J. C. Hardwick, 588
Public Health: in Brazil (Dr. João de Barros Barreto), 631
  in Chile (Dr. Pedro Aguirre Cerda), 118
  in Great Britain (Sir George Newman), 599
  in Peru (Dr. Constantino J. Carvallo), 371
  Research, 345
Public Schools in Great Britain, The (Prof. J. D. Bernal, Prof. P. G. H. Boswell, Prof. S. Brodetsky, Prof. J. Chadwick, Prof. W. E. Le Gros Clark, Brig.-General F. A. E. Crew, Prof. C. Lovatt Evans, Prof. B. Farrington, Prof. C. B. Fawcett, Prof. P. Sargant Florence, Prof. P. F. Frankland, Prof. Lancelot Hogben, Prof. Julian Huxley, Dr. R. K. Kelsall, Prof. R. D. Laurie, Dr. Joseph Needham, Prof. R. Pascal, Prof. J. A. Ryle, Dr. F. Soddy, Dr. H. G. Stead, Prof. Geo. Thomson, Prof. F. E. Weiss, Prof. F. Wood-Jones), 351; (Prof. N. K. Adam), 433; (Rev. Canon Spencer Leeson), 524
Public Services, Problems of Personnel in, 357
Public Utilities in Reconstruction, 329
Publication of Scientific Research carried out in Industry (Dr. K. G. Denbigh), 322; (Dr. Norman R. Campbell), 408
Punjab Plantations, On the Biology of the Parasites of the Shisham Defoliators in the (R. N. Mathur and C. F. C. Beeson), 552
Purification: (Partial) of Cell Growth-Promoting Principles in Adult Tissue Extract (H. Werner and Dr. L. Doljanski), 660
  and Chemistry of Penicillin (Dr. J. R. Catch, Dr. A. H. Cook and Prof. I. M. Heilbron), 633
Purpose, Design and (Prof. Frederic Wood Jones), *review* by Prof. A. D. Ritchie, 69
Purser (John Mallet) lecture for 1943 to be delivered by Prof. J. M. O'Connor, 766
Putrefaction in Cattle Hides (Dr. D. Jordan Lloyd), 439
Pyrethrum: Extracts, A Method of Physiological Assay of (Dr. Otto Lowenstein), 760
  Flower, A New Active Constituent from (D. N. Roy and S. M. Ghosh), 153
  Sprays (Dr. E. A. Parkin), 124

QUALIFICATIONS of the Social Psychologist, 741
'Quality' Control of Production, Statistical (Sir Charles Darwin), 117
Quality of Glassware, Cords, Surface Finish and the (A. J. Holland, Eric Preston and Prof. W. E. S. Turner), 27
Quaternary Carbon Atom, Long-chain Acids containing a (A. J. Birch and Sir R. Robinson), 553

RABBIT Kidney, Glucose Excretion by the (Prof. T. W. T. Dillon), 492
Race: and Racism (Ruth Benedict), *review*, 192
  Reason! and Rubbish (Dr. Gunnar Dahlberg), translated from the Swedish by Prof. Lancelot Hogben, *review*, 192
Racism, Race and (Ruth Benedict), *review*, 192
Radiation: in the Atmosphere, Absorption and Emission of, 144
  from Flames (Prof. W. T. David), 407
  from the Sun (Dr. C. E. P. Brooks), 226
  (Cosmic) and Penetrating Showers, Connexion between the Penetrating Non-ionizing Component of (Dr. L. Jánossy and Dr. G. D. Rochester), 633
  (Luminous) from Hot Gases (Prof. W. T. David), 291
  (Ultra-violet) with Special Reference to Lethal Effects (J. R. Harris), 88
  Pattern of the Human Voice (D. W. Farnsworth), 583
Radical Chain Reactions, Free (J. R. E. Smith and Prof. C. N. Hinshelwood), 295
Radicals, Counting Free Alkyl (M. H. Feldman, J. E. Ricci and M. Burton), 740
Radio Board, set up by the Government, 733
Radio Circuits, Frequency Stability of, 765
Radio Committee, Production Planning and Personnel, 733; Operations and Technical, 733
Radio Interference, Man-made (R. A. Shetzline), 265
Radio Engineers, Reference Data for (Standard Telephones and Cables, Ltd.), 346
Radio Research: (Dr. R. L. Smith-Rose), 493
  for the Services, 733
Radio Transmitter (30 kw. Short-Wave Radio) for All-American Cables and Radio, Inc. (F. D. Webster and R. E. Downing), 52
Radio-Waves (Ultra-Short), Diffraction of (Dr. J. S. McPetrie and J. A. Saxton), 292
Radioactive Sources in the Earth, Heat Energy from (William D. Urry), 30
Radio-Frequency Waves, Velocity of (Dr. R. L. Smith-Rose), 477
Radiography (Industrial), Royal Photographic Society symposium on, 519
Radiological Library, Sale of a (Museum Book Store), 545
Radiotherapy, Peruvian National Institute of, 401
R.A.F., New Light Day-Bomber for the, 733
Raman Effect: in a Single Crystal of Naphthalene (T. M. K. Nedungadi), 741
  Fluorescence, Light Scattering and the, Symposium on, 741
Raman Frequencies of Aniline, Diethyl Sulphide, and two Binary Liquid Mixtures (Dr. C. S. Venkateswaran and N. S. Pandya), 741
Raman Spectrum of 1,3,5-Triphenyl Benzene (Prof. S. K. Mukerji and Laksman Singh), 347
Raman's Theory of Specific Heat of Crystals (Dr. M. Blackman and Prof. M. Born), 55
Rancagua, Earthquake on June 29, 207
Range Management, Sampling Methods in Forestry and (F. X. Schumacher and R. A. Chapman), *review* by Prof. R. A. Fisher, 196
Ras Shamra, Excavations at (Commander Schaeffer), 327
Rat, Collection of Eggs from the Fallopian Tube of the (I. W. Rowlands), 267
Rat's Incisor Tooth (Enamel Organ of the) in Vitamin E Deficiency (Prof. J. T. Westoll), 122
Rats: treated with 1:2:5:6-Dibenzanthracene, Formation of Hæmolymph Nodes in (Dr. A. Lasnitzki and Dr. D. L. Woodhouse), 660
  and the War (Dr. Charles White), 287
  (Brown) (*Rattus norvegicus*), A Relative Census Method for (Dennis Chitty), 59
Reaction Data, Energy-Level Treatment of (Dr. J. W. Baker), 551
Reactions, Free Radical Chain (J. R. E. Smith and Prof. C. N. Hinshelwood), 295
Reason! Return to, an Essay in Political Diagnosis (Dr. Geoffrey Bourne), *review* by Dr. Joseph Geoghegan, 472
Reason (Race,) and Rubbish (Dr. Gunnar Dahlberg), translated from the Swedish by Prof. Lancelot Hogben, *review*, 192

Rebuilding Great Britain, 410
Reconstruction: (Federation of British Industries), 33
  Anglo-American Relations in, 613
  in the Civil and Municipal Services (G. D. H. Cole), 331
  in Great Britain: The People, 685; The Land, 685; International Aspects, 685

  of Personality, Foundations for a (Dr. Andras Angyal), *review* by J. Drever, 418
  Politics and Service (John Petrie), 179
  and Religion, *review* by the Very Rev. W. R. Matthews, 130
  (The Applications of) to Rural Planning (appointment of a British Association Committee on), 346
  in Soviet Russia (edited by Dr. Joseph Needham and Jane Sykes Davies), *review* by J. G. Crowther, 647
  and Technology in the Soviet Union (Faculty of Science of Marx House), 659
  for Victory (Association of Scientific Workers conference on), 429
  and Total War (Association of Scientific Workers conference on), 427
  (Organization of) for War, 301
  and the War Effort, 641 ; (Prof. J. D. Bernal), 263 ; (Parliamentary and Scientific Committee on), 316
Sciences, The Place of Social Biology in the (Sir Walter Langdon-Brown), 527
Scientific Collaboration Committee, Anglo-Soviet, 285
Scientific Exhibition in Moscow, 369
Scientific Films : Conference on, 230
  and their Use in the Teaching of Physics (Physical Society discussion on), 691
  Soviet, 342
Scientific (Specialist) and other Journals, Advice on the disposal of (Association of Special Libraries and Information Bureaux), 401
Scientific Life, The (Dr. John R. Baker), *review* by Prof. John L. Myres, 164
Scientific Literature for Enemy Prisoners of War (Dr. John R. Baker), 408
Scientific Men in War-Time, 65, 116
Scientific Mission (Cultural and) to China, 369, 426
Scientific Research carried out in Industry, Publication of (Dr. K. G. Denbigh), 322 ; (Dr. Norman R. Campbell), 408
Scientific Workers (Cambridge) and the War (Cambridge University Branch of the Association of Scientific Workers discussion on), 186 ; (Sir Robert Robinson), 269
Scientific and Technical Board, Central: Association of Scientific Workers meeting to discuss proposals for a, 265
  Association of Scientific Workers conference on, 383
  Parliamentary and Scientific Committee to consider the setting up of a, 288, 316
Scientific and Technical Resources, Utilization of, 189
Scientists : Face the World of 1942 (Karl T. Compton, Robert W. Trullinger and Vannevar Bush), *review* by Prof. Willis Jackson, 5
  of the United Nations and the War Effort (Association of Scientific Workers conference on), 602
Scotland, Plant Diseases in (R. W. G. Dennis and C. E. Foister), 294
Scott Committee on Land Utilization in Rural Areas, Report of the, 441, 448
Scottish Lake Dwellings, 639
Scrap, Recovery of Metals from (Sir Harold Hartley), 594
Sea, Minerals, Old and New, from the (Dr. E. F. Armstrong), 453
Sea Waves : their Growth and Subsidence (P. J. H. Unna), *erratum*, 20
  the Water Movement (P. J. H. Unna), 581
Seasoning of Timber (Alexander L. Howard), 638
Security Plan, The Beveridge, 753
Seedling Growth, Effect of the Moon on Germination and (M. Mather), 630
Seismicity of New Zealand (R. C. Hayes), 243
Seismology, Bibliography of (Ernest A. Hodgson), Vol. 13, No. 11, January to June, 1942, 459
Sectors (Rotating) in Stellar Photometry (Donald A. MacRae), 436 ; (L. F. Barcus), 436
Selachine as a Colour Neurohumour in Sharks (G. H. Parker), 182
Selenanthren Molecule, Folding of the (Raymond G. Wood and Gordon Williams), 321
Self (Body and), One and Inseparable (Percy A. Campbell), *review*, 446
Self-incompatibility in Certain Diploid Potato Species (G. P. Carson and H. W. Howard), 290
Sense Organs, Mechanism of Sensitivity Changes of (Prof. Krikor Kekcheev), 491 ; (Dr. G. W. Scott Blair and F. M. V. Coppen), 580
Sensitometry since Hurter and Driffield (Dr. S. O. Rawling), 519
Separators (Battery), Indian Woods for, 630
Serum : Micro-determination of Calcium in (P. F. Holt and H. J. Callow), 553
  (Blood), Drying Blood Plasma and, 18
Service, Science, Politics and (John Petrie), 179
Services : Radio Research for the, 733
  (Women's), Education and Leadership in the, 415
  (Three Women's), Report of the Committee on Amenities and Welfare Conditions in the, 415
Sexuality in *Dugesia tigrina* (syn. *Planaria maculata*) (Dr. E. D. Goldsmith), 351
Shape of Subjective Space (Shaun M. Cox), 349 ; (S. L. Walkden), 662
Shares (Fair) for All (Political and Economic Planning Broadsheet No. 192), 629
Sharks, Selachine as a Colour Neurohumour in (G. H. Parker), 182
Shillong Plateau, Relict Vegetation of the (Dr. N. L. Bor), 213
Ship among Waves, Drifting Force on a (T. E. Havelock), 352
Shipbuilding and Research, 693
Shisham Defoliators in the Punjab Plantations, On the Biology of the Parasites of the (R. N. Mathur and C. F. C. Beeson), 552
Shoot Organization : in Dicotyledon and Monocotyledon, 95
  of *Heracleum Sphondylium* (C. P. Majumdar), 95
Showers (Penetrating), Connexion between the Penetrating Non-ionizing Component of Cosmic Radiation and (Dr. L. Jánossy and Dr. G. D. Rochester), 633
Sirius and its Companion (Robert G. Aitken), 572
Siting of Power Stations (F. Favell), 53
Skeletal Remains (Late Medieval) from Holderbank in the Solothurn Canton (Dr. Lucia Graf), 150
Skeletons (Anatomical and Anthropometric Description of four) from Darvela near Truns (Prof. Otto Schlaginhaufen), 150
Skull (Horse's), Evolution in the (E. C. R. Reeve and P. D. F. Murray), 402
Sky : in North Africa, 764
  (Night) in August, 119 ; in September, 265 ; in October, 372 ; in November, 519 ; in December, 632 ; in January, 766
Skye, 'Bog-Butter' from (M. C. Burkitt), 29 ; (Prof. J. Ritchie), 29
Slide Rule Cursor, The (W. R. Ashby), 379
Sludge Process (Activated), Role of Protozoa in the (S. C. Pillai and Prof. V. Subrahmanyan), 525 ; (Dr. S. H. Jenkins), 607
Smallpox in the United States, 288
Smithsonian Institution, Annals of the Astrophysical Observatory of the (C. G. Abbot, L. B. Aldrich and W. H. Hoover), Vol. 6, 226
Smoke from their Fires, the Life of a Kwakiutl Chief (Prof. Clennan S. Ford), *review* by Mrs. K. Rishbeth, 193
Smut (Loose) of Wheat, Solar Treatment of (J. C. Luthra), 231
Snail (Carnivorous) *Euglandina rosea* (Férussac), Food, Eggs and Young of the (William Marcus Ingram), 663
Sneezing, Folk-lore Treatment of (Dr. Leo Kanner), 118
Social Biology : in Education (British Social Hygiene Council conference on), 555
  in the Sciences, The Place of (Sir Walter Langdon-Brown), 527
  Now and in the Future (W. L. Sumner), 555
  for Teachers in Training (Mrs. E. J. Hatfield), 555
Social Contract, A New (D. Caradog Jones), 692
Social Force, The Church as a, 399, 469
Social Framework, The, an Introduction to Economics (Prof. J. R. Hicks), *review* by G. D. H. Cole, 617
Social Geography in India, *review* by Prof. H. J. Fleure, 334
Social Insurance and Allied Services (Sir William Beveridge), 753
Social Medicine : 129
  at Oxford, 116
Social Psychologist, Qualifications of the, 741
Social Reporting (Tom Harrisson), 293; (The Reviewer), 293
Social Security and Social Services, 585
Social Service in Great Britain, Finance and, 629
Social Status of the Psychologist and its Effect upon his Work (Prof. T. H. Pear), 741
Social Stratification (English), Psychological Aspects of (Prof. T. H. Pear), 465
Social Survey, A New, *review*, 475
Social System, Disease and the (Arthur Guirdham), *review* by Dr. H. G. Baynes, 247
Society : Evolution in, 527
  (Indian), Matriliny in, *review* by Prof. J. H. Hutton, 644
Sociological Aspects of Production Committees, 1
Sociology : An Introduction to (Prof. John Lewis Gillin and Prof. John Philip Gillin), *review* by Prof. George Catlin, 590
  as an Academic Discipline, *review* by Prof. George Catlin, 590
Sodium Chlorate in Weed Destruction, Catalysts for (Dr. Ernest A. Dancaster), 737
Soil Characteristics, Human Activities and (Kenneth L. Robinson), 24
Soil Cracks, Function of (Dr. A. Sreenivasan), 409
Soil Physics, Soil Cultivation, and Cultivation and Crop Yields (Dr. B. A. Keen), 264
Soil-less Cultivation (Prof. R. H. Stoughton), 174
Solar Eclipse (The Total) of October 1, 1940 (Dr. A. Hunter), 512
Solar Eruption and Magnetic Storm of March 1–2, 1942 (H. W. Newton), 183 ; (M. A. Ellison), 183 ; (P. Laurie), 183
Solar Treatment of Loose Smut of Wheat (J. C. Luthra), 231
Soldering Electrical Joints, 371
Solders, Tin (S. J. Nightingale), second edition, *review*, 8
Solids of Revolution, Stress Distributions in (R. V. Southwell), 353
Solubility of Calcium Phosphate, Effect of an Enzyme from Kidney on the (Dr. H. Lehmann), 603
Solothurn Canton, Skeletal Remains from Holderbank in the (Dr. Lucia Graf), 150
Solutions of Macro-molecules (Prof. E. K. Rideal), 602
Something to Look Forward to, a Suggestion for a New Social Contract (Lady J. Rhys Williams), 692
Sorghums, Genetics of the (G. N. Ayyangar), 663
Sound : A Text-book of (Dr. A. B. Wood), second edition, *review* by Dr. W. H. George, 248
  Reproduction, Technical Basis of (Dr. L. E. C. Hughes), 629
Source Beds of Petroleum (Parker D. Trask and H. Whitman Patnode), *review*, 194
South Africa, Nemerteans from, and a Note on *Lineus corrugatus* M'Intosh (Dr. J. F. G. Wheeler), 583

South American Indians of the Gran Chaco, Life among the (Sir John Graham-Kerr), 555
Southeast: Early Horizons in the (Prof. William S. Webb), 156
  Late Horizons in the (T. M. N. Lewis), 156
Southern Ocean (Kerguelen and the), Nemerteans of (Dr. J. F. G. Wheeler), 583
Southwest (Early Horizons in the), Discoveries in Sandia Cave and (Frank C. Hibben), 156
Soviet Life in War and Peace, National Exhibition of, 519
Soviet Russia, Science in (edited by Dr. Joseph Needham and Jane Sykes Davies), *review* by J. G. Crowther, 647
Soviet Scientific Films, 342
Soviet Scientific Work on Potatoes (Prof. A. T. Lysenko), 456
Soviet Union, Science and Technology in the (Faculty of Science of Marx House), 659
Space (Subjective), Shape of (Shaun M. Cox), 349 ; (S. L. Walkden), 662
Spain, Earthquake on July 12, 118
Spaniotoma minima, Mating Swarm in a Chironomid (Dr. N. H. E. Gibson), 268
Specialist Scientific and other Journals, Advice on the disposal of (Association of Special Libraries and Information Bureaux), 401
Specific Gravity of *Calanus finmarchicus* (Dr. F. Gross and J. E. G. Raymont), 327
Spectra : of γ Cassiopeiæ, Changes in the (Miss E. M. Peachey), 353
  (Absorption) of 3-4 Benzpyrene (Prof. F. Weigert), 56
  (Selective Excitation of) by the High-Frequency Discharge (Prof. R. K. Asundi and Nand Lal Singh), 123
Spectrographic Observations at the Total Eclipse of October 1, 1940 (R. O. Redman), 353
Spectrometer, Portable Mass (John A. Hipple, jun.), 111
Spectroscopic Methods, The Study of the Atomic Nucleus by (Dr. S. Tolansky), 487
Spectroscopy in Astrophysics, 601
Spectrum (Raman) of 1, 3, 5-Triphenyl Benzene (Prof. S. K. Mukerji and Laksman Singh), 347
Spencer (Herbert) lecture on The Values of Science to Humanity (Prof. A. G. Tansley), 104
Spiders : and their Life History and Habits (E. A. Robins), 242
  Amber (A. Petrunkevitch), 183
Spinach Beet, A Red Colouring Matter from the Green Leaves of (Ralph J. B. Marsden), 580 ; (H. G. Baker), 689
Spinning Top, Dynamics of a (J. Miller), 436
Spiral Coiling (Plane) : Tracing (F. Wolverson Cope), 210
  of Small Fossil Lamellibranchs, Optical Projection as an Aid in Studying (Lieut. A. T. J. Dollar), 57
Sprays, Pyrethrum (Dr. E. A. Parkin), 124
Stability (Frequency) of Tuned Circuits (C. W. Eggleton), 765
Stabilizer (Differential Electronic) for Alternating Voltages (Arvon Glynne), 740
Stamps (Postage), Astronomy on, 229
Standardization of Industrial Electrical Instruments (Lieut.-Col. K. Edgcumbe), 734
Standards : International Systems and (Sir Richard Gregory), 429, 620
Star : Atlas for the Latitude of Egypt (H. E. Hurst, M. R. Madwar and A. H. Samaha), second edition, 764
  System, An Important Binary (Dr. R. M. Petrie), 545
Starch and Cellulose in Herbivora, Microbial Factors in the Digestive Assimilation of (Frank Baker), 479
Starlings and Foot-and-Mouth Disease (Dr. W. S. Bullough), 739
Stars : Distribution of the (Dr. Bart J. Bok), 459
  (A-Type), The Problems of the (Otto Struve and P. Swings), 370
  Orbital Variable (P. M. Ryves), 436
Statesman's Year-Book for the Year 1942, edited by Dr. M. Epstein, *review*, 222
Static Conversion of Direct Current to Alternating Current with Grid-Controlled Mercury-Arc Mutators (R. Feinberg), 664
Statistical ('Quality') Control of Production (Sir Charles Darwin), 117
Statistical Methods, Modern, *review* by Prof. R. A. Fisher, 196
Statistics : (Mathematical), The Fundamental Principles of (Hugh H. Wolfenden), *review* by Prof. R. A. Fisher, 196
  The New Population (Dr. R. R. Kuczynski), 487
Steel (Bullet-proof), Electrical Production of (A. G. Arend), 298
Steelworks, Dolomite Bricks for use in (T. Swinden and J. H. Chesters), 184
Stellar Photometry, Rotating Sectors in (Donald A. MacRae), 436 ; (L. F. Barcus), 436
Stellar Structure (Dr. T. G. Cowling), 20
Stellate Chromatophore in the Polychæta (Dr. M. V. Lebour), 209
Stereochemistry, The Basis of, 572
Steric Promotions and Inhibitions of Polarizations (Dr. G. Baddeley), 178
Sticky Materials, 'Tack' and (British Rheologists' Club and the Printing and Allied Trades Research Association discussion on), 159
Stonar (The History of) and the Wantsum Channel (Dr. F. W. Hardman and W. P. D. Stebbing), 20
Stones, Indian Precious (Dr. L. A. N. Iyer), 458
Storage (Food) and Transport, 217
Stratification (English Social), Psychological Aspects of (Prof. T. H. Pear), 465
Strength : of Materials (Prof. S. Timoshenko), second edition, Part 1 : Elementary Theory and Problems ; Part 2 : Advanced Theory and Problems, *review*, 645
  (Intrinsic Electric) and Conductivity of Varnish Films and their Variation with Temperature (A. Morris Thomas and Miss M. V. Griffith), 770
  (Tensile) of Water and Liquid Structure Theory (Dr. R. S. Silver), 605
Stress : Distributions in Solids of Revolution (R. V. Southwell), 353
  Systems in Aeolotropic Plates (A. E. Green), 238
Stresses (Working) for Indian Timbers (V. D. Limaye), 571
Structure : of Complex Fluorides (J. L. Hoard and M. B. Williams), 27
  of 'Diphenylene' (Wilson Baker), 210 ; (Dr. C. A. Coulson), 577
  of Galactic Clusters (George Alter), 664
  of Lead Chromate (S. B. Brody), 740
  of Salivary Gland Chromosomes (M. Kodani), 352
  of Urea and Thiourea (W. D. Kumler and G. M. Fohlen), 664
  and Rotation of Galaxies (Dr. A. Hunter), 169
Structure, Stellar (Dr. T. G. Cowling), 20
Structure (Crystal) of Oxyhæmoglobin (M. F. Perutz), 324
Students : in the United States; Reservation of, 316
  (University) and Military Service, 732
  and Designers, Materials for, *review*, 645

Study : of Decapod Larvæ, *review*, 474
  of Delinquency, *review* by Prof. Cyril Burt, 361
  of Race, *review*, 192
Stump Production in Madras Teak Nurseries (A. L. Griffith), 743
Stuttgart Rheintalgraben, Earthquake on February 22, 175
Subcutaneously Implanted Tablets of Synthetic Œstrogens, 'Ghost' Formation in (Dr. S. J. Folley), 403
Subject Index to Periodicals, 1940, *review*, 8
Subjective Space, Shape of (Shaun M. Cox), 349 ; (S. L. Walkden), 662
Sudan : Fevers in the, 631
  Medical Services of the, Report of the Director for 1940, 631
Sugar Metabolism, Influence of Potassium on (Dr. S. N. Farmer and D. A. Jones), 768
Sugar-Cane, A New Heavy-yielding and Strong-growing Variety of (Ch. Kh. Mohammad), 231
Sulphanilamides : (Effect of) on the Growth of Micro-organisms in Presence and Absence of *p*-Aminobenzoic Acid (Sten Wiedling), 290
  and Experimental Tuberculosis (Bertil Sjögren), 431
Sulphur (Behaviour of) in Rubber (G. G. Winspear), 31
Sumner To-day, Selected Essays of William Graham Sumner, with Comments by American Leaders, edited by Prof. Maurice R. Davie, *review* by Miss E. I. Black, 417
Sun : in the Galaxy, Motion of the (Ralf E. Wilson), 400
  Radiation from the (Dr. C. E. P. Brooks), 226
Sunspots during 1938, Mean Areas and Heliographic Latitudes of (Dr. H. Spencer Jones), 353
Superconductivity and Liquid Helium II (Dr. J. G. Daunt and Dr. K. Mendelssohn), 604
Surface Finish (Cords,) and the Quality of Glassware (A. J. Holland, Eric Preston and Prof. W. E. S. Turner), 27
Surfaces, The Physics and Chemistry of (Prof. Neil Kensington Adam), third edition, *review* by Prof. Eric K. Rideal, 730
Surges (Voltage) caused by Contactor Coils (J. R. Taylor and C. E. Randall), 664
Survey : Maps and (Arthur R. Hinks), fourth edition, *review*, 675
  A New Social, *review*, 475
  of World Resources (Sir Harold Hartley), 686
Survey Atlas (Regional) of the Croydon District (Croydon Natural History and Scientific Society), 766
Surveys (Anthropological), War-time Uses of, 385
Sweden : Oil-bearing Plants in, 176
  Production of Synthetic Rubber in, 764
Swedish Archæology, 573
Swedish Army, Health of (General Ivar Holmquist), 371
Switches, Effects of Contact Resistance on Temperature Rise in (R. W. J. Cockram), 355
Switzerland : Anthropology in, 150
  Earthquakes registered during February, March, April and May, 175 ; Earthquakes registered in, 545 ; Earthquake at Mürtschenstock on June 25, 345 ; Earthquake reported on October 30, 602
Synthesis : of Cellobiose (W. T. Haskins, R. M. Hann and C. S. Hudson), 553
  of Vitamins by Intestinal Bacteria (P. R. Burkholder and I. McVeigh), 553
  (A New) of X-Ray Data for Crystal Analysis (Dr. H. Lipson), 25
Synthetic Œstrogen (A New) with Prolonged Action when Given Orally (Dr. J. M. Robson, A. Schönberg and Dr. Wadie Tadros), 22, 429
Synthetic Rubber : *review* by Dr. W. J. S. Naunton, 751
  Formation of a Committee on, 150
  (Production of) in Sweden, 764
Synthetic Rubbers, Modern (Dr. Harry Barron), *review* by Dr. W. J. S. Naunton, 751
Syrian (North) Archæology and Old Testament Sources (M. C. Burkitt), 327
Systematics of Polychæta, 609
Systems and Standards, International (Sir Richard Gregory), 429, 620

TABLE : of Deformations (British Rheologists' Club), 602
  (International) of Stable Isotopes (Dr. F. W. Aston), 515
'Tack' and Sticky Materials (British Rheologists' Club and the Printing and Allied Trades Research Association discussion on), 159
Tajuulcom Volcano, Guatemala, Earthquakes on April 11, 401
Tanganyika, Earthquake in the Songea District on November 8, 602
Taxonomy, Mycological, 609
Tea Leaves as a Maintenance Food for Animals (W. King Wilson), 199
Teacher of Nations, The (edited by Dr. Joseph Needham), 602
Teachers in Training, Social Biology for (Mrs. E. J. Hatfield), 555
Teaching of Colour in Schools (E. G. Savage), 422
Teak Nurseries (Madras), Stump Production in (A. L. Griffith), 743
Technical Basis of Sound Reproduction (Dr. L. E. C. Hughes), 629
Technical Board (Central Scientific and): Association of Scientific Workers meeting to discuss proposals for a, 265
  Association of Scientific Workers conference on, 383
  Parliamentary and Scientific Committee to consider the setting up of a, 288, 316
Technical Resources (Scientific and), Utilization of, 189
Technical Glossaries, Russian-English, 543
Technology (Science and) in the Soviet Union (Faculty of Science of Marx House), 659
Telephone Apparatus, Suppressing High-frequency Disturbances from (M. E. Krom), 265
Telephone Cable, Determining Colour in, 428
Telephony (Transoceanic), Future of (Dr. Oliver E. Buckley), 60
Telescopes, The Third Earl of Rosse and his (M. A. Ellison), 458
Telophase Split in Todea, Demonstration of the (Dr. I. Manton), 547, 736; (Dr. P. T. Thomas), 736 ; (Dr. P. C. Koller), 736
Temperature : of the Atmosphere (Dr. T. G. Cowling), 686 ; (Dr. L. Jánossy), 686
  Control (A. J. Ansley), *review* by J. H. Awbery, 727
  (Intermediate) Modification of $Ni(NO_3)_2.6NH_3$, Formation of a Double Crystal Aggregate and the Structure of the (S. H. Yü), 347
  Rise in Switches, Effects of Contact Resistance on (R. W. J. Cockram), 355
  Variation of Diffuse Scattering of X-Rays by Crystals (Prof. M. Born and Dr. K. Lonsdale), 490
Temperatures (Flame Gas), Influence of Water Vapour on (Prof. W. T. David and J. Mann), 521
Tensile Strength of Water and Liquid Structure Theory (Dr. R. S. Silver), 605

Test Animal for Tubercular Infection, The Golden Hamster as a (Dr. J. Ungar), 432
Testing (Analysis and) of Coal : (H. J. Hodsman), 667
  in relation to its Properties and Utilization (Melchett Lecture by Dr. Arno Carl Fieldner), 372, 667
Tetraploid Shoots in *Brassica oleracea*, Origin of (H. W. Howard), 739
Tetrapods (Primitive), Relationships of some (Dr. T. S. Westoll), 121 ; *errata*, 176
Tetrathionate, Bacterial Reduction of (M. R. Pollock, R. Knox and P. G. H. Gell), 94
Theory : of Relativity, Introduction to the (Prof. Peter Gabriel Bergmann), *review* by Prof. W. H. McCrea, 359
  of X-Ray Diffraction (Prof. P. P. Ewald), 450
Thermal Diffusion, Separation of Isotopes and (Prof. James Kendall), 136
Thermal Diffusion Factor, Change of Sign of the (K. E. Grew), 320
Thermal Fluctuations in Resistances, The E.M.F. of (M. Surdin), 550
Thermal Vibrations : and X-Ray Scattering (Miss K. Sarginson), 295
  and Scattering of X-Rays (M. Born), 353
Thermionic Valve Circuits (Dr. Emrys Williams), *review*, 74
Thermochemical Calculations (Dr. Ralph R. Wenner), *review* by Prof. D. M. Newitt, 37
Thermodynamics and Chemical Engineering, *review* by Prof. D. M. Newitt, 37
Thiazoline (Oxazoline and) Rings in Proteins (S. Blackburn, W. R. Middlebrook and H. Phillips), 57
Thinking, Austerity, *review* by Miss E. I. Black, 417
Thiourea (Urea and), Structure of (W. D. Kumler and G. M. Fohlen), 664
Thio-Ureas as Goitrogenic Substances (T. H. Kennedy), 233
Thomson (Sir Joseph J.) First Memorial Lecture, 279
Thorium Family, Experimental Evidence of the Existence of Element 85 in the (Mrs. Alice Leigh-Smith and Dr. Walter Minder), 767
Tides, Admiralty Manual of (Dr. A. T. Doodson and Comdr. H. D. Warburg), *review* by Dr. G. R. Goldsbrough, 615
Timber, Seasoning of (Alexander L. Howard), 638
Timber-Seasoning Kilns (M. A. Rehman), 127
Timbers : Studies of the Identification of (Alexander L Howard), *review* by Dr. C. R. Metcalfe, 533
  (Indian), Working Stresses for (V. D. Limaye), 571
  (Michelia) for Aircraft, 630
  Photographic Identification of, *review* by Dr. C. R. Metcalfe, 533
Time, The Conquest of (H. G. Wells), *review* by Prof. Herbert Dingle, 444
Time Series (Economic), The Analysis of (Harold T. Davis), *review* by Dr. A. L. Bowley, 335
Time and the Universe, a New Basis for Cosmology (Dr. F. L. Arnot), *review* by Dr. G. C. McVittie, 308
Tin Economy in Cable Jointing (J. T. Lowe), 458
Tin Solders (S. J. Nightingale), *second edition*, *review*, 8
Tissue : (Effect of Extracts of Heterologous Adult) on Cell Growth *in vitro* and their Use in Wound Healing (Prof. L. Doljanski, R. S. Hoffman and E. Tenenbaum), 23
  Culture Technique, Use of Desiccated Chick Embryo in (Dr. R. I. Shukoff), 461
  Extract (Adult), Partial Purification of Cell Growth-Promoting Principles in (H. Werner and Dr. L. Doljanski), 660
  (Living), Estimation of Moisture in (E. G. Hallsworth and R. L. Reid), 524
Tissues (Living), The Mode of Occurrence of Fatty Acid Derivatives in (J. A. Lovern), 294
Titration Explained, *review*, 504
Toad (Common), Feeding of the (O. R. Barclay), 376
Todea, Demonstration of the Telophase Split in (Dr. I. Manton), 547, 736 ; (Dr. P. T. Thomas), 736 ; (Dr. P. C. Koller), 736
Tolerance Curve, Intravenous Glucose (G. D. Greville), 522
Tomato Fruit, Respiratory Channels in the (K. A. Glendinning), 26
Tomatoes : Chlorosis in (B. T. Cromwell and J. G. Hunter), 606
  Experiments on Growth of (Dr. M. A. H. Tincker), 630
  (Green), Vitamin C from (Frank Wokes and Joan G. Organ), 523
Tonanzintla, Mexican National Astrophysical Observatory at, dedication marked by the issue of postage stamps, 229
Tooth (Enamel Organ of the Rat's Incisor) in Vitamin E Deficiency (Prof. J. T. Westoll), 122
Top (Spinning), Dynamics of a (J. Miller), 436
Torch and Crucible, the Life and Death of Antoine Lavoisier (Sidney F. French), *review*, 619
Towns : (New) After the War (F. J. Osborn), 87
  Our (Elizabeth E. Halton), *review*, 447
Toxicity (Relative) of Insecticides (Dr. J. R. Busvine), 208

SOCIOLOGICAL ASPECTS OF PRODUCTION COMMITTEES

THE critical importance of establishing effective relations between management and workers in relation to production has been noted in more than one report of the Select Committee on National Expenditure, and one of the main objects of the Joint Production Advisory Committees now being set up is to assist in such integration and to eliminate the misunderstandings which arise when, for example, workers are unaware of the real causes of idle time and other interruptions in production. This factor, it should be noted, is increasingly liable to operate as the mobilization of our industrial man-power and woman-power approaches its limits. There is less and less margin to prevent an interruption at one point causing delays and even more serious interruptions elsewhere.

The value of such attempts to give the workers a true picture of the situation has been well illustrated in a recent visit of a deputation from a local trades and labour council to an ordnance factory, which was reported in the House of Commons. The deputation had full liberty to talk to any employee or shop steward, and the conversations described in the report show how unfounded most of the complaints of idle hours, idle machines and lack of sympathy between management and workers proved to be, and how high an opinion the deputation formed of the personnel and welfare management of the factory compared with private industry. Sir Frederick West, chairman of the North-Western Regional Board of the Ministry of Production, commenting on unfair and inaccurate statements in the report of the Amalgamated Engineering Union on war production with reference to management, confirmed that the Regional Board's own experience in dealing with allegations and rumours criticizing management had indicated that they were mostly unfounded or grossly exaggerated. More substantial grounds of criticism, it is true, are revealed in the investigations of complaints regarding two royal ordnance factories described in the Ninth Report of the Select Committee on National Expenditure, but even here the report shows that the troubles were very largely those which are invariably experienced in starting a factory with an excessive proportion of untrained workers. The superintendents of both factories were fully alive to the problems which confronted them and were doing their utmost to overcome difficulties. Many of the allegations were considerably exaggerated and on most of the matters action had already been taken, though the Select Committee's recommendations, particularly in regard to supervision, the co-ordination of inspection and production, the keeping of records, the handling of transport difficulties and the abolition of Sunday work have a much wider pertinence than in the two factories investigated.

The value of the Joint Production Committees as a weapon of democracy, enabling workers and employers to collaborate in one common and urgent drive, receives powerful support in a recent broadsheet of Political and Economic Planning (P E P). The workers, accepting the responsibility of full participation in the war effort, are beginning to think in terms of 'we' instead of 'they', and are proving that as efficient collaborators they can be far more than mere mechanical factors of production. By enlisting the intelligence and experience of the men who work with their hands, these Committees enable us to make fuller use of the man-power of Great Britain, and they should in this way do something to meet that shortage of efficient and experienced managers which in places so seriously handicaps our war effort.

If at the same time the fresh brains give an impetus to co-operation and improve the efficiency of production, the Committees will prove themselves unmistakably weapons of war, with the advantage that they could equally prove weapons for winning the peace. The importance of the Production Committees should not in fact be judged only by the extent to which they improve the organization of production. They should be judged also by the changes they effect in the attitude of workers and managements to each other in production relations. It is probable that the Committees will strengthen rather than undermine the trade union movement; they may also lead to a more open mind and a wider outlook on industrial and social affairs on the part of organized labour. This should facilitate the handling of some of the problems of post-war reconstruction as much as it will immediately further the contribution of the workers of Britain in the world-wide struggle for democracy.

The Joint Production Committees are an essentially new development, the strength and significance of which cannot yet be adequately judged, and there are still many obstacles in the way of their success. Some managers oppose them as a superfluous addition to an already widely ramified administrative system. Some trade unionists, on the other hand, are resisting the new Committees on the ground that they are instruments of that industrial collaboration which they have always fought.

Political and Economic Planning has therefore rendered a national service in bringing out so promptly a broadsheet which outlines the facts and sets this new development in its true perspective against the Whitley reports and the experience of works committees and councils, as well as sketching the growth of Production Committees up to their official recognition in February 1942. Success or failure of individual committees will undoubtedly depend largely on the personality of the chairman. He must be capable of bringing out the best in the members, encouraging them to speak frankly, and inspiring open-mindedness, independence and energy. Trade unionists, however, have also a great responsibility for the success of the Committees, and they should not fail to realize the important part which the Committees may play in promoting efficiency. Moreover, this development is so clearly in line with movements in the industrial life of our allies, the United States of America and the U.S.S.R., that it may be of great significance in furthering co-operation with these great countries after the War in the task of restoring order and hope and a new standard of living to the shattered world.

While the main purpose of these developments is to promote the efficiency of our war effort, they have a long-term objective which should not be overlooked. We cannot hope to build a new and more equable social order after the War without mutual confidence and trust between management and workers. The standard of industrial relations which best serves the nation's immediate purpose in war is exactly that which best promotes social justice and order in times of peace. There could be no better illustration of this than the coal industry, in which the attitude of both workers and employers has often been a serious threat to the war effort. What is no less apparent to every impartial observer is the high price which the nation has had to pay for such intransigence and sectionalism in the past. The repercussions on our social economy as a whole in the past twenty or thirty years make the coal industry the very first place where the Government should be required to prove that private and sectional interests shall no longer be allowed to obstruct the national purpose.

The highly suggestive report on "Fatigue of Workers: its Relation to Industrial Production" which was published last year in the United States by the Committee on Work in Industry of the National Research Council, is of particular interest in this connexion. It is no disparagement of the scientific or technical work on the elimination of fatigue, the improvement of conditions of work and prevention of accidents, to emphasize, as this report does, that such physical conditions may be of secondary importance compared with the psychological or social conditions. Neglect of the latter has undoubtedly been a main factor in the persistence of such unhappy conditions in the coal industry.

The National Research Council's report is in the tradition of that line of fundamental research on which Dr. Elton Mayo lays such stress in his stimulating volume "Human Problems of an Industrial Civilisation", and it includes some account of those researches at the Western Electric Co. at Hawthorne which are described in that book as well as in T. N. Whitehead's "The Industrial Worker" and elsewhere. This section of the book, together with the chapter which summarizes and discusses Mr. C. I. Barnard's book "The Functions of the Executive", give it a significance far beyond that indicated by its title, and it merits careful study by all those concerned with the improvement of industrial relations, whether from the point of view of war production or of reconstruction after the War.

One of the most striking features of the book is the illustration it gives of the lack of knowledge of each others' minds and purposes on the part of management and worker even in such a progressive firm as the Western Electric Co. The investigators formed the opinion that management really knew very little about what constituted good supervision, or what the employees thought about their conditions of work. This lack of communications is responsible for the failure to secure the desired results even when good working conditions have been established. An executive order without the participation of the workers may be, and often is, ineffective.

The report points out that, pre-occupied with the continual study of its methods so as to make them more efficient, and making inaccurate assumptions about the motives and behaviour of employees, management gives a series of orders which are transmitted through a hierarchy of supervisors to those doing the physical work. At that level the action does violence to the workers' sentiments and is felt to be a threat to their informal organization, and restrictive or protective action by the workers results. Because technical organization is geared to rapid change, while social organization cannot change rapidly, the latter tends to protect itself by retarding change.

The question of communication itself, however, is both upwards and downwards. Where it is fully established and the worker understands the changes that are proposed and the purposes to be served, co-operation becomes effective and the difficulties tend to disappear. Where for any reason communication both upwards and downwards is good, satisfaction is high and authority is strong.

It is therefore of the utmost importance for management to ensure that the generalizations on which it must in practice rely are accurate and not weighted too heavily by the logic of efficiency and economics. Equally, it must recognize the way in which authority arises out of the collaboration of the individuals affected. The first responsibility for the establishment of communications is that of management downwards, for failure in that direction is at once the cause of failure in the upward direction from the worker.

The second outstanding point which emerges from this report and the researches at the Western Electric Co. is the demonstration of the significance of informal organization. Such organization always exists in conjunction with formal organization, but the importance of its two functions are only now becoming recognized: to transmit information and understandings which, for one reason or another, cannot be transmitted by the formal communication system, and to allow means for individuals to escape from certain effects of formal organizations which tend to disintegrate the personality. The place of the social group in industry presents indeed a most promising field of investigation, for the autonomous groups of M. Dubreuil's scheme are by no means the only means of eliminating the sense of frustration or repression of individuality which large-scale mechanized industry, however well directed, is apt to engender.

No one can put down this highly suggestive report without realizing how much we have yet to learn from the formal study of human organization, both in furthering the war effort and in building the peace. What Mr. Barnard has to say about the aspects of executive work which are aimed at securing co-operation are also important. Purpose is indeed the unifying principle of organization, and experience of nearly three years of war, endorses all that the report observes on this point. What is required to date is in fact to interpret the nation's purpose and its needs so that they are understood by every citizen upon whom it calls for service. Only such understanding and acceptance can call forth the immense moral as well as physical effort required to carry the United Nations to victory. In Great Britain no less than in the United States, the committee of the National Research Council has made a noteworthy contribution to creative thinking and to social and industrial efficiency which has both short- and long-range significance.

CRATER LAKE

Crater Lake: The Story of its Origin

By H. Williams. Pp. xxii+100+10 plates. (Berkeley, Calif.: University of California Press; London: Cambridge University Press, 1941.) 10*s*. 6*d*. net.

WE have good reason to be grateful to both Canada and the United States for their contributions to peace as well as to war. Among their most precious gifts are the national parks of the glorious West, which they have consecrated for all future time to the service of humanity. The larger examples, such as Jasper, Yellowstone and the Grand Canyon, harbour men and bears on terms reminiscent of the Garden of Eden. The park of Crater Lake, Oregon, covering roughly 300 square miles, of which a tenth is submerged, is too small to share in this particular distinction; but the blue of its lake and the gay tints of the surrounding cliffs lead some of its devotees to acclaim it as the most beautiful place in the world. Perhaps these enthusiasts have never visited that other park which contains Lake Louise in Alberta; perhaps they say 'most beautiful' when they really mean 'most fascinating'. Be this as it may, all who have had the privilege of visiting Crater Lake admit its rare loveliness, combined with an intellectual stimulus of quite exceptional quality. It is scarcely possible to stand on the rim of the crater and avoid asking the question: How did it happen?

Fortunately, the two great countries concerned, each within its own boundaries, in the conduct of the national parks of the West clearly recognize the educational possibilities of these institutions. In the United States, J. C. Merriam, chairman of the appropriate committee of the National Academy of Sciences, has helped and encouraged Howel Williams to produce the booklet under notice, which goes far to satisfy the most inquiring visitor. The booklet is excellent in plan, language and illustration—including two coloured plates by Paul Rockwood—excellent, in fact, in all respects but price.

The booklet is in two parts: the first aims at describing the changing scenes of the past as though recorded by a succession of eye-witnesses; the second at presenting some of the evidence in the form of a discussion between a Park Guide and a group of questioning tourists.

The first part is quite unusual. It adopts in language the technique of the illustrator, who occasions no surprise if he does portray in picture, model or diorama the details of an imagined scene of long ago, where only broad outline has really been established. Thus Howel Williams tells of the growth of Mount Mazama, and of the destruction of its summit to yield a caldera site for Crater Lake, with the same confidence in print as Paul Rockwood manifests in paint. Here is what we read of the entry, be it remembered in prehistoric times, of Mount Mazama upon the phase of explosive activity that served as prelude to the stage of caldera formation:

"The opening day was clear and the morning light shone brilliantly on the ice around the summit. Suddenly there was an ominous rumbling underground, and a moment later a plume of steam rose from the crater. The slumbering volcano had awakened."

One is reminded of the younger Pliny's account of the resurrection of volcanic activity at Vesuvius, A.D. 79, an account which many historical critics in after-centuries considered fiction until at last it was confirmed by excavation of Pompeii and Herculaneum. Howel Williams's story of Mount Mazama is, of course, a geological novel, written by an author who has felt at liberty to clothe the essential facts of research in trappings of make-believe so transparent that they can be trusted to deceive no intelligent student.

The second part of the booklet marks, as Rastall has recently pointed out in the *Geological Magazine*, a reversion to the procedure of Plato's dialogue. A Guide is beset with every type of question that might occur to an inquisitive visitor. I agree with Rastall that the ordeal is handled very successfully.

Here is the main theme: the caldera which holds Crater Lake, six miles in diameter, obviously replaces the central portion of the volcanic peak to which the name Mount Mazama has come to be attached in geological literature. The old, old question arises: Has the replacement occurred through explosion or subsidence? The Guide supports with figures the verdict that has long been accepted, namely, that subsidence has been predominant. He estimates that 17 cubic miles of old volcano have disappeared; and in the volcanic ashes spread over the country at about the same time as the caldera formed he can only find 1½ cubic miles of fragments of old volcanic material.

Having decided that 15½ cubic miles of volcano have sunk in the process of caldera formation, the next main question is: How was room provided to receive the downfall? Here it must be understood that the old volcanic fragments just referred to are a minor feature in ashes consisting mainly of contemporaneously formed pumice. This latter has the following bulk composition expressed in cubic miles: 2 of crystals + 3 of glass + 5 of bubbles.

Neglecting the bubbles, the Guide concludes that the expulsion of this pumice made room for 5 only of the 15½ cubic miles of downfall. The remaining 10½ cubic miles he accommodates by postulating a sudden withdrawal of a corresponding volume of magma through injection into subterranean cracks.

From this distance, one is tempted to inquire whether it is justifiable to omit the enormous output of vapour in striking a volume-balance between expulsion and downfall. Admittedly the 5 cubic miles of bubbles owe most of their volume to reduction of pressure; but presumably they represent only a small fraction of the volatiles actually released.

Let us now take up another interesting point. The Guide is able to show that the pumice-ashes first of all fell like snow through the air to lie, as a comparatively thin sheet, indifferently on hill and dale; but that later outpourings of similar material rolled along the surface as glowing avalanches to choke valley bottoms in the Peléan style, which was first correctly interpreted in the West Indies by Flett and Tempest Anderson. The Guide quite convincingly bases his recognition of the glowing avalanche type upon the restriction of the material to valley bottoms. I remember, however, that in 1933, without the assistance of this criterion, which depends upon a survey of the district, I felt sure that I was looking, in one of these valleys, at a cooled representative of what had been a glowing avalanche, because it showed well-developed columnar jointing. A glowing avalanche is, after all, a close relation to a lava flow.

Still another point raised by the Guide concerns the texture of the widespread fallen ash. The material is definitely coarser at the top than at the bottom. The Guide deduces from this observation an increase of explosive violence during the eruption, thus permitting of carriage of bigger and bigger fragments high into the air. Again, at this distance from the evidence, one may ask whether a reverse inference is not preferable; whether in fact there was not in the initial stages so strong a blast of gas as to produce a finer spray of pumice than could be maintained later in the proceedings. On this alternative interpretation, the final boiling over of the glowing avalanches, which, by the way, carry the biggest fragments of all, would be a sign of still further failure of gas supply, not, as the Guide imagines, the culmination of a crescendo.

If space permitted, it would be possible to draw many apposite comparisons between Crater Lake and its ancient deeply eroded predecessors at Glen Coe, Ben Nevis and Mull. One obvious conclusion is that Mount Mazama may have sunk much more coherently than is suggested in the sections that illustrate this booklet.

Now for a last remark. The Guide shows that the glowing avalanches contain most of their crystals in their upper layers. This is a repetition of a condition found by Kennedy in certain composite lavas of Scotland, which, strongly porphyritic above, are non-porphyritic below. The inference in either instance is clear: the porphyritic material now at the top of the bed of ash (or lava, as the case may be) must, before extrusion, have underlain the accompanying non-porphyritic material in the volcanic pipe. The Guide is certainly justified in his interpretation of this relationship as evidence of settling under gravity.

In conclusion, I wish to thank the author and all concerned for a booklet in every way worthy of its great subject. Readers on turning to its pages will realize how inadequate is the present restricted notice.

E. B. BAILEY.

THE HISTORY OF SCIENCE

A History of Science and its Relations with Philosophy and Religion

By Sir William Cecil Dampier. Third edition, revised and enlarged. Pp. xxiii+574. (Cambridge: At the University Press, 1942.) 25*s*. net.

SIR WILLIAM DAMPIER is to be congratulated on the appearance of a third edition of his history of science. The first edition, published in 1929, was quickly sold out, a second appearing early the following year. This edition has long been out of print. For a large, rather expensive book, which scarcely appeals to specialists, which is no help in passing examinations, which, though meant for the general reader, will be tackled only by the tougher members of the species, this is most encouraging. It shows there is a genuine interest in the history of science. Indeed, since 1929 a great deal has been done on the subject. Dr. Sarton's monumental work is going ahead; the journal *Isis* has published much valuable material, and excellent studies of special subjects and special periods have appeared. However, here is a comprehensive view in a single volume that need fear no rival for many years to come.

Comparison of the first and the new edition shows that many passages have been revised and generally improved. To avoid altering the numbering of the pages passages have also been omitted, and a few of these are perhaps to be regretted. There are many new citations of literature which greatly increase its value as a work of reference. A new chapter, the eleventh, has been added to record the scientific advances of the period 1930–1940. Many readers will turn to this first and most unfairly judge the book by it. It does seem a bit scrappy to read; it could scarcely be otherwise. The only alternative to this chapter would have been a complete rearrangement and almost complete re-writing of more than a hundred pages, and those probably the hardest to write. In any subject the nearer the historian comes to his own day the harder it is to be comprehensive and judicial. In science, where the rate of discovery in many branches in the years between the wars was becoming breathless, the difficulties are appalling. It is safe to predict that almost anybody reading this last chapter will conclude that his own pet subject scarcely gets its fair share and that certain subtle points have been dealt with rather crudely, but that other subjects are treated very fairly or even get more attention than they deserve.

The first thirty years of the twentieth century were the most spectacular in the whole history of science. The fourth decade did not appear so spectacular, but who knows what is to come? True, what Sir William Dampier has to record is mainly steady progress in many branches and no startling revolutions. The sky is clear, but the barometer is not steady. In biology none of the old controversies are really settled. Detailed knowledge accumulates, too fast almost, but general principles are lacking. In physics it is much the same. Physical theory, if the outsider may venture a remark, goes from bad to worse. There used to be one fundamental simplicity to cling to, namely only two ultimate, permanent, massive entities, electrons and protons (with photons as additional honorary members). One seemed to understand how these were necessary and sufficient. Now there are admitted to be several more, there is no apparent reason against any number of ultimate entities, and they are not so permanent after all.

Classical mechanics was the outcome of studying a narrow range of velocities and magnitudes (the moon and the apple.) By this over-simplification of the problem it succeeded in finding simple and useful working rules, but anything like a complete solution meant considering also the very fast, the very small and the very large. So also, in studying the general problem of the nature of matter, classical physics and chemistry were confined to a very narrow, easily accessible range of conditions and found useful but complex, numerous and ill-co-ordinated working rules. Twentieth-century physics, by going outside this range and investigating intense electric fields, extremely low densities, extremely high densities, extremes of temperature, and so on, has obtained much wider understanding and simpler generalizations; but it is pretty clear that nothing like finality has yet been reached.

The mathematics of physical theory always made it too difficult for the outsider to understand properly, but he used to comfort himself with the thought that the experts were agreed and therefore must be supposed to know. Now even this comfort seems to have gone. Moreover suggestions that some or all of the fundamental laws of physics are *a priori* seem to be gaining ground. Strong objections have been made to this notion, but the objectors do not seem very clear why they object. To work out a completely deductive cosmological theory is evidently possible in principle; it only needs brains. At least one empirical generalization would be necessary before it could be applied, but there seems to be no inherent reason, apart from imperfections in the theory, why there should be more than one. After that all the rest would be *a priori*.

If doubts and difficulties and unsolved problems accumulate, that is no reason to despair of science. Anyone who does despair and longs for the lost infallibility of the nineteenth century is making the false assumption that the material universe is such a paltry affair that a mere twenty-six centuries of intermittent investigation is enough to get to the bottom of it. This appears to be one of the morals to be drawn from the history of science. The other seems to be that, though no problem is finally completely solved, ingenuity and hard work can produce solutions that are valid within limits and within those limits a permanent gain. A. D. RITCHIE.

APPLICATION OF SCIENCE TO HUMAN NEEDS

Scientists Face the World of 1942

Essays by Karl T. Compton, Robert W. Trullinger, Vannevar Bush. (Rutgers University, Publications of the 175th Anniversary Celebration, No. 3.) Pp. vi+80. (New Brunswick, N. J.: Rutgers University Press, 1942.) 1.25 dollars.

THIS small book consists of three essays by Karl T. Compton, Vannevar Bush and Robert W. Trullinger, and three commentaries on these essays by Harvey N. Davies, Detlev Bronk and S. W. Fletcher. Although Dr. Bush relates his contribution primarily to the biological and Dr. Trullinger to the agricultural aspects of scientific development, the theme of each of the essays is the problem of how best to apply the enormous accumulation of scientific information in an economic manner to meet human needs and desires.

Dr. Compton discusses the progress which has been made in the fundamental sciences of physics, chemistry and biology and in certain of the applied sciences, and relates the extent to which it has been necessary to discontinue work in these fields in favour of investigations bearing more directly on the prosecution of the war effort. This is directing the attention of large numbers of men of science both in Great Britain and the United States to the sort of problems which confront the engineer acting in his normal capacity, and the benefit will be of long standing. These men of science are contributing to the development of new engineering tools such as special types of thermionic valves, alloys, plastics, etc., and their influence will accelerate considerably the already established trend away from the empirical towards the analytical approach to the solution of engineering problems.

The most interesting feature of the essays is, however, the broader use of the title of engineer than has been accepted as yet in Great Britain. The agricultural engineer discussed by Dr. Trullinger is by no means unknown in Great Britain, but even if the biological engineer, whose function is described by Dr. Bush, has been conceived, one has not heard of the introduction or consideration of the special courses of study which are evidently being contemplated in the United States. Whether we shall consider it necessary in due course to make special provisions for the training of those men whose function it will be, according to Dr. Bush, to supervise and control the application of the results of scientific research and the products of technical development to the biological aspects of the food, fermentation and clothing industries, sanitation, housing and medicine is uncertain. Whether we should call him a biological engineer is doubtful. We have accepted the chemical engineer, however, to advantage and at least we should avoid lagging unduly in our consideration of the needs in question.

The comparison with chemical engineer presented by Dr. Bush covers a point which it will be well to keep in mind from the beginning. He says: "When the chemical industry first began its phenomenal growth in this country there were primarily two types of professional men involved, chemists who manipulated test tubes and retorts in laboratories, and mechanical engineers who built and operated pumps and tanks in plants. What more natural than to create chemical engineers by giving them a scanty chemical training, and an equally scanty training in mechanical engineering ? The result was not a happy one, and it was not improved until a group of men, notably William Walker, created a new philosophy for chemical engineering based on the concept of the unit process. The chemical engineer of to-day is a far different individual from a mere hybrid chemist-mechanical engineer; he has a whole approach and a set of thought processes which are uniquely his. He differs from the chemist in much the same way that the electrical engineer differs from the applied physicist, and he has avoided being superficial in two subjects by creating a third in which he can be decidedly thorough.

"Much the same sort of evolutionary procedure is to be expected as the profession of the biological engineer develops. He does not need to attempt to create a new approach to the science of biology, nor does he need to essay a novel recast of the economics of business practice. He very much needs to produce a unique handling, at the professional level, of the combination of applied biology and its practice in industry."

Dr. Bush's essay does not leave one with a very clear picture of the intended function of the biological engineer and of the precise nature of the education and training he should receive. He says, however: "the engineer who designs and builds a plant in which a wide range of chemicals are produced and processed by biological methods will need to know something of bacteriology, of molds, of fungi, something of chemistry, a bit about energy transformations, perhaps some thermodynamics, and a good deal of mechanics. It would not be at all surprising, the way things are going, if he would need to know something of electronics. He will not be a master of all these, and if he attempts to become thus omniscient he will defeat his own purpose. He can, however, learn the entrances and how to go further."

It seems that special courses of study for agricultural engineers are available in forty-eight land-grant institutions. In the opinion of S. W. Fletcher, however, few of these have developed as yet "a distinctive curriculum having a characteristic core of studies" and he echoes views now obtaining wide acceptance in Great Britain in similar connexions when he writes:

"Here is the primary reason why so many graduates in agricultural engineering fail to meet the stern requirements of industry. It is common observation that those who have had adequate training in basic subjects with a moderate amount of training in specialised techniques are better able to adapt themselves to the constantly shifting requirements of agriculture and industry than graduates of highly specialized curricula."

"The charter of the land-grant institutions sets as their goal 'a liberal as well as a practical education'. A liberal education is defined by the Society for the Promotion of Engineering Education as 'The knowledge and practice of those intellectual pursuits, principles of living, and avocations which tend to broaden human interest and sympathies and to contribute to personal happiness and social welfare'. The public has a right to expect that graduates in agricultural engineering will be more than good technicians." WILLIS JACKSON.

WORLD AFFAIRS

Out of the Ashes

A Survey of the Unhappy Lands and a Design for International Harmony. By Thorburn Muirhead. Pp. 231. (London: Robert Hale, Ltd., 1941.) 10s. 6d. net.

THIS is the first attempt to put together the state of the world, after the Russian war but not including the Japanese. It is mainly a sketch of the British Empire, and is useful as showing the universal vigour of the island conquerors as soon as they took up the trail in the sixteenth century. It becomes an empire, and conquest was involved, but there was never any idea of world dominion. Trade, profit, adventure and the settlement of the New World led Great Britain by the end of the nineteenth century to be the premier Power in the world and an object of offence to other great Powers. *Hinc illæ lacrimæ*. With our earlier rivals—the French—a sensible agreement was made which at the moment is responsible for our command in Egypt and Suez. But the later rival was only piqued by jealousy of Great Britain. There was always a grasping and hectoring tone in Prussianized Germany, and in the Nazi regime that temper has been aggravated by the foulest stream of cruelty and lying which history relates.

The result is that, with the exception of Japan, all the threatened and occupied nations rally to the champions of world freedom. But they are at the moment helpless and the United States of America, the U.S.S.R. and Great Britain have to face the threat and restore the world.

Here Mr. Muirhead is favourable to us, though earlier in his book one might think a British conqueror or settler no better than he should be. Clearly the settlement of stronger people among the uncivilized must lead to friction. But an honest narration of the facts makes it clear that Britain civilized, and is far the best colonizer in the world. The Dutch have worked well with us in the now most contested part of the front.

Mr. Muirhead is quite clear that we shall win, or at least that Germany must lose: "the financial and economic scales are too heavily loaded" against her. But the task before us—perhaps for some years—is the restoration of order when the Nazi chain is broken. For this purpose the Atlantic Charter strikes the note. In the post-war world there must be some international authority, and Mr. Muirhead would be content if we did the policing. He sketches a scheme of free-trade roads which would enable the smaller nations to trade and to gain their own necessities without the loss and vexation which attend the present system. We wish such a plan well, but before that we have to break the hideous yoke which has been imposed by the Nazis until they reached the barrier of Russia.

It is a long and determined struggle and we need to keep something of the crusader, with all the fire and finish of modern war. It is to be hoped and believed that the United Nations will perform it.

F. S. MARVIN.

THE 'CELLULOSE AGE'

An Introduction to the Chemistry of Cellulose

By J. T. Marsh and Dr. F. C. Wood. Second edition. Pp. xv+512+24 plates. (London: Chapman and Hall, Ltd., 1942.) 28*s*. net.

THE influence of chemical research on the industrial applications of cellulose has in general been slow in making itself felt as compared with results in many other industries. This, perhaps, is due partly to the fact that the cellulose industries have hitherto been regarded primarily as the domain of the engineer; although a contributory and more likely reason is the complexity of the chemistry of cellulose. It is not surprising, therefore, that the important advances in this branch of chemistry which have taken place during the past twenty-five years are putting cellulose on an entirely new footing as a material of industry, and it may well be that the post-war period will herald a 'cellulose age' marked by many varied and interesting developments of a chemical rather than engineering nature.

Several weighty arguments justify this view. First, as Cross and Bevan wrote in 1895, "cellulose is the predominating constituent of plant tissues, and may be shortly described as the structural basis of the vegetable world". The industrial applications of cellulose are therefore, like agriculture, a direct link between man and the plant world. Secondly, the achievements and possibilities of the cellulose industries are impressive in both magnitude and scope. Thus what may be described as the primary cellulose industries, such as timber, textiles (including rayon) and paper, are all essential features of modern civilization, as war-time shortages have demonstrated only too well; while the secondary industries and their ramifications, though still in their infancy, cover an extremely wide field ranging, for example, from the plastics, fine chemicals and organic solvents derived from the waste liquors of the cellulose pulping processes, to the explosives, cattle fodders, sugars and other fermentation products obtainable directly from cellulose itself. There are many other examples.

It is not to be inferred that this volume covers all the fields indicated above; that it should result in reflections of this nature, however, is a measure of the importance of its subject and of the success of the authors, as well as the fullest justification for its existence—if justification is needed for a second edition which appears within three years of the first. The authors certainly have again done their work very well and have presented an up-to-date résumé of the subject, despite the great handicap of the rapid development of our knowledge in this field. This handicap is strongly apparent when, for example, the molecular weight of cellulose is considered; six different methods of determination are described, but the values obtained show marked variations, and this applies both to cellulose from the same source and to the results of different workers using the same method.

In this connexion there are occasions when the reader feels that he would like a little more critical comment from the authors themselves on contradictory results rather than bald statements, however accurate and concise, of the work of others; this is important in a book dealing with such a difficult subject, and intended (as the preface states) primarily as a guide to the younger chemist entering the cellulose industries. On the other hand, if the book is judged mainly for its value as a summary of current knowledge on the subject, it is impossible to praise it too highly. Little work of importance has been overlooked, and some of the few omissions (such as the convenient cupri-ethylene diamine reagent for the determination of the viscosity of cellulose) are probably the result of the long time-lag between publication and 'publicity' which exists at present.

Those who, like the reviewer, incline to the wider view of the importance of cellulose will be a little disappointed at the bias shown towards textiles, and in particular to cotton cellulose. Thus, for example, wood pulp (which may contain more α-cellulose than cotton and is the basic material of large sections of the rayon and paper industries) receives little mention, and then only in passing. Again, while the chemical and physical properties of cellulose are fully discussed, the effects on these of mechanical action (such as the beating operation in paper manufacture) are not referred to; yet they make valuable contributions to problems such as the structure of cellulose fibres, including those of textile origin. A chapter dealing with this very important aspect of the subject would certainly be a valuable feature of future editions. This, however, is a personal opinion, arising possibly from an opposite bias to that of the authors, and it in no way precludes the reviewer from confidently recommending the book to all concerned with cellulose as well as to the 'ordinary' chemist.

It is necessary only to add that apart from the discussion of the constitution and structure of cellulose at an earlier stage, the general scope and arrangement of the material are the same as those of the first edition. There are, however, some eighty additional pages and several extra illustrations. Misprints noted in the first edition have been corrected, but a few more have crept in, and some of the abbreviations used for references (for example, B.C.I.R.A. and J.T.I.) will probably be meaningless to many readers and do not occur in the explanatory list at the end of the book. The standard of production shows very little deterioration from that of pre-war times.

JULIUS GRANT.

Tin Solders

A Modern Study of the Properties of Tin Solders and Soldered Joints. By S. J. Nightingale. (Research Monograph No. 1.) Second edition, revised with inclusions of Results of more Recent Research, by Dr. O. F. Hudson. Pp. 118. (London: British Non-ferrous Metals Research Association, 1942.) 10*s*. 6*d*.

OF all the common alloys used by the engineer, solder is by far the most expensive. Further, as a result of the temporary loss of the main tin-producing area in the Empire, the utmost economy in the utilization of this metal, an essential ingredient in most solders, is imperative. The present time is, therefore, particularly appropriate for the publication of a second edition of a valuable little compilation which has been out of print for some time.

In its new form, this volume contains considerably more information than did the first edition, particularly in connexion with the metallography and properties of these alloys, and it speaks well for the excellence of the first edition that the part which deals with the more practical considerations and the choice of a suitable solder has required practically no modification.

As one example of the utility of this book, both from the point of view of the information it gives, as well as from that of economy of tin, may be instanced the solder used for production of wiped joints in electric cable sheathing. An earlier specification for such material required about 35 per cent of tin with not more than 0·5 per cent of antimony. It has now been found that an alloy with 30–31 per cent of tin which may contain up to 6 per cent of antimony has superior mechanical properties, gives joints of reduced porosity, and, in the experience of the workers, is easier to manipulate.

Dr. O. F. Hudson, the new editor, and the publishers have done a very useful piece of work.

A Supplement to the Yorkshire Floras

By the late F. Arnold Lees. Edited by C. A. Cheetham and Dr. W. A. Sledge. Pp. v+134. (London and Hull: A. Brown and Sons, Ltd., n.d.) 6*s*. net.

THE flora of Yorkshire has been described in the volumes on West Yorkshire by F. A. Lees (1888), East Yorkshire by J. F. Robinson (1902) and North Yorkshire by J. G. Baker (1906). Some thirty years ago, Lees collected the additional records and incorporated them in a manuscript entitled the "Vegetation of Yorkshire and Supplement to the Floras of York". This extensive manuscript included, however, so much theoretical discussion relative to the facts embodied that sufficient support could not be found for its publication, though the Yorkshire Naturalists' Union always hoped that the included records might be made available for botanists. This undertaking has now been achieved by Mr. Cheetham and Dr. Sledge and published under the auspices of the Union.

Mr. Cheetham has a very wide knowledge of the flora and has been connected for so long with all aspects of the work of the Union that no one could have been found better able to undertake the work of extracting all reliable data from Lees's manuscript and from the records of the Union. Dr. Sledge has added very many recent records and has revised all the material in the light of the most recent developments in nomenclature and grouping of genera. The volume includes a complete list of the recorded species, including aliens, casuals and escapes which are distinguished typographically from natives, with new recorded localities and points of interest concerning changes in distribution. This cheap and relatively small volume does great credit to the amount of work put into its preparation in order to condense the material to valuable essentials.

The Observer's Book on Astro-Navigation

By Flight-Lieut. Francis Chichester. Part 4. (Observer's Books, No. 5.) Pp. 152. (London: George Allen and Unwin, Ltd., 1942.) 4*s*. 6*d*. net.

IN this, the fourth and concluding portion of Flight-Lieut. Chichester's book on astro-navigation, a number of important matters are dealt with. These include a description of the flying-boat sextant and the errors that can be introduced into the observations by flight accelerations. The advantage of taking a number of observations at short regular intervals is shown and a brief description is given of the median-marking sextant. The aid to navigation given by running down a position line, when the sun is the only object available for observation, is illustrated by the record of observations on an actual flight; the method is of special value for flights over the sea, where no landmarks are available for fixing position. The important subject of curved flight corrections is dealt with in some detail. If accurate navigation is required, it is essential to apply corrections for curved flight, due to the rotation of the earth, or to the course steered not being a great circle, or to gyro-wandering. The account of these corrections is somewhat confused, though the method of applying them is clearly explained and illustrated by examples.

The four parts of this book together provide a useful summary of the principles and methods of astro-navigation. Written by a skilled navigator, they contain many practical hints, and any navigator who has mastered their contents cannot fail to benefit from them.

H. S. J.

The Subject Index to Periodicals, 1940

Pp. xi+230. (London: The Library Association, 1942.) £3 17*s*.

THE Subject Index of Periodicals, 1940, issued by the Library Association, publication of which has been considerably delayed by enemy action, covers 534 periodicals, other than those, with some important exceptions, covered by the *Agricultural Index*, *Engineering Abstracts*, *Engineering Index*, *Index Medicus*, *Journal of the Society of Dyers and Colourists*, *Photographic Abstracts*, *Bibliography of the Royal Meteorological Society*, *Science Abstracts*, *Journal of the Textile Institute*, and the *Revue des Géologie, Minéralogie et Crystallographie*. The number of entries has been diminished owing to the curtailment of the supply of Continental periodicals since 1940, and some of the files of American periodicals are also incomplete. The volume, however, is only about one sixth thinner than the normal volume. The Index is compiled on the plan of the dictionary catalogue, articles being entered under specific headings, in alphabetical order. Explanatory matter is added in square brackets where the titles do not sufficiently indicate the subject of articles. Since September 1940, the editor and his staff have been accommodated in the National Library of Wales, Aberystwyth, although part of the work still has to be done in the British Museum Library.

MORALE

By JOSEPH GEOGHEGAN

"If thy people go out to battle against their enemy."
1 Kings, 8, 44.

MORALE is a feeling of confidence and competence in the conduct of an enterprise.

This definition needs some enlargement. Morale is a feeling, an emotional state, not an intellectual opinion, and is thus like all emotions a variable; it can be either good or bad. It is a feeling of confidence, confidence in the outcome, confidence in cause, comrades and leaders. It includes a feeling of competence, of personal capability, self-confidence, if you wish. Lastly, morale requires a positive issue, relatively a major one, for the term has no bearing in situations without such an appeal.

Application of the word may properly be made to an individual or to an aggregate of individuals. The latter, however, must possess one definite characteristic, that of being homogeneous in the sense of free association, purpose and sympathy, as in a street crowd, a regiment or a nation. The purport of the following remarks is intended to consider more particularly aspects of morale in the case of the last.

It is important at the outset to recognize clearly that the motivations of a crowd differ radically from those of an individual. The herd instinct, a very strong one, has to be taken into account. While this is active at all times to a slight extent, encouraging behaviour in harmony and consistence with the welfare and custom of the community, it can become, and indeed would appear to be so constructed as to be capable of becoming, a paramount feeling. This is particularly the case in the presence of danger. The ranks close up, there is a reduction of personal individuality, the unicellular organism has, as it were, become part of a multicellular whole.

Furthermore, this effect brings about a reversion to impulse and action of a more primitive type, more of a childish pattern, more of the deeper mind-stuff, the unconscious. The mechanism involved is interesting and pertinent to the issue. The herd instinct operates by an intensive heightening of the suggestibility of all the component units, the people in the crowd. This feature requires emphasis. Suggestibility is definitely outside or beyond the control of the individual and is not necessarily agreeable in any sense with his own interests. It is a simple sharp response immediate and direct to the stimulus of the moment, akin perhaps to a conditioned reflex. The strength of suggestion in a group is very strong; the individual has little or no option but to obey, for it is the emotional side which is employed, not the rational. When the individual merges in the mass his rational mind sinks with him; he ceases to be himself. It is a waste of words to appeal to the intelligence of a crowd; it is only their emotions that listen.

Arising out of, and indeed a component part of, the instinct of the herd is the need of leadership. The pack at all times demands a strong dominant personality in front; in the presence of trial or danger the need becomes insistent and incidentally much more decisive. We then feel the rightness of the right man in the right place with a confidence past question.

With the leader the members of the herd feel a strong identification; he exemplifies in himself the genius of the pack, something louder, coarser, bigger, but something utterly and vividly the presentment of each and everyone. His qualifications are curious; he need have served no long apprenticeship, he need have no particular intellect, but he must have personality and character. He must have the prestige which follows not the reality of achievement but the appearance of it. Finally, he must still be the common man, like the wolf leader, only one jump ahead of the rest. All the members want to see clearly in front the visible embodiment of their own feelings.

After these brief references to certain aspects of the basic material, the factors influencing morale may be considered. Both the physical and psychological sides are involved but the effects of the former are more evident in a detrimental sense.

Factors Tending to Increase Morale

Bearing in mind that morale refers to an emotional tone, the first and probably the most important factor tending to improve confidence and competence in the conduct of an enterprise is *the sense of unity* engendered by the increased contact with our fellowmen, the closing of the ranks. This has both its physical and psychological sides and indeed they are very closely intermingled. In ordinary civil life man is gregarious only in a narrow range, in his work, profession, game, club and so on; in times of danger or distress the need for support, the strength in unity, and vice versa, the insecurity of isolation, converge. They encourage the need for the company of our fellow creatures by the bond created in a renewed community of interest. This fresh warmth of feeling again fortifies courage and fills the individual with a new and special strength. It is the heightening of this impulse which leads to a notable breakdown of social distinctions and local prejudices. Comradeship and the team-spirit are the visible evidence of a common purpose. There is a strong exaltation of both the patriotic and the human sides, all the more so when the combative and aggressive feelings are allowed approved outlet in identification with a greater whole.

This sense of fulfilment in unity gives a new steadfastness and energy to each member of the pack; it increases altruism and tends to add a moral strength to morale. For the national interests so obviously link up with the highest moral aims and purposes of humanity. They are thus strengthened by the indirect appeal to the noblest aspirations of the individual, the conviction of a righteous purpose, the strong association of duty with a deep religious feeling. These feelings may be consciously enhanced by the deliberate inculcation of a high moral aim, by the 'indoctrination' of the public in a sacred fellowship, by the stress laid upon a positive ideal which directly relates national need with a spiritual purpose.

Conversely, the enemy personifies all evil. The same instinct of the herd that brings the ranks shoulder to shoulder for the common good, that gains strength with every fresh evidence of national righteousness, vehemently denies to the enemy any shred of justification. He so blatantly represents the negation of all good, he so deliberately runs counter to every law of God or man, he carries with him such a foul string of barbarities that it becomes only right and proper to smite him hip and thigh. Old Testament phrases come readily to the tongue to express the feeling.

The groundwork for this sense of unity will have been prepared not only by education in the young in the geography and history of their native land, but also by the cultivation of a political philosophy that brings the genius of the nation into the closest relations with the highest ethical principles. Self-defence is not enough, it is too negative; there should have been a long and careful preparation tending to dignify the responsibilities, nay the duties, of the nation with a positive, a moral goal. Phrases such as "England, My England", "this blessed plot, this earth, this realm, this England", the white man's burden, the commonwealth of nations, and so on, become eventually part and parcel of everyday thought, and are accepted as self-evident truisms. It will not, of course, be overlooked that this attitude is by no means the sole prerogative of any one nation; an identical purpose is apparent in the use of such words as Aryan, superman, *Herrenvolk*, *Lebensraum*, etc. The principle has very general application.

Second to this sentiment of unity comes the feeling of *confidence*. This includes many of the relationships of the herd animal, notably so when herd consciousness is stimulated afresh in time of trial. Certain aspects stand out: these are cause, comrades, leaders and equipment.

Confidence in the cause wherein all are engaged implies two angles of approach: confidence in its essential rightness and confidence in its result. The first depends largely upon the depth of that intense emotional feeling we call patriotism; this again arises from a continuity of effects which may be summarized as nature and nurture, which co-operate to encourage the sense of nationality. The famous lines beginning "Breathes there a man with soul so dead" may be recalled to illustrate the passionate association of patriotism with what is regarded as the highest side of mankind. Conversely, from the very strength and urgency of this feeling springs the sharp resentment at the insolence of alien attack. "Ourselves alone!"

This sense of nationality, this patriotism, wells up 'as it were' under pressure from great depths; it is a trained and disciplined emotion, partaking of a certain splendour and assured of a genuine approval. The ground has been prepared not in one but in many generations and needs but a touch to set it all aglow with faith in the right and in the result. Then speaks in no hesitating voice confidence in the high abiding virtue of our cause and the sweet certainty of success. It may again be remarked that there is no material difference between the feeling in Moscow, Madrid, Manchester or Munich.

Confidence is also felt in comrades. This will be at once enhanced by the direct recognition of an equality of service and an equality of sacrifice. The positive evidence of mutual resolve and support, the visible activity on the part of everyone around to the same great purpose, all for one and one for all, encourages the feeling of comradeship and co-operation, which again reacts to strengthen personal endeavour: "Duke's son, cook's son, son of a millionaire" and so on. In service alone can be found peace and satisfaction; if it be denied, discouragement, anxiety and restlessness are felt.

But an equality of sacrifice plays an equal part. The press of conscription on everyone, the fracture of all social distinctions in the ranks, the subordination of the individual pattern in the need to keep step, the acknowledged severity of an income tax that strikes at incomes not at wages, and perhaps most real of all, the daily lists of casualties—names from both the castle and the cottage—bring out afresh mutual trust and *esprit de corps*. Everyone can do his bit!

Confidence must further be felt in leaders and equipment. It will be at once understood that the multiple millions of a modern nation need not a leader, but leaders. There will be many graduations of place and post, all of which have weight and effect. Selection on the part of any section of the public, if allowed free play, will be spontaneous and accurate; it will be natural and will choose a natural leader. Conversely, the capacity to select efficient deputies must be one of the cardinal qualities of leadership.

Equipment again can have decided influence on confidence. The recognition of efficiency to our personal knowledge in the tools to hand, not only the ones *I* use but the ones *we* use, at once improves confidence in every sense. The dark silence of the Navy in the North Sea, the swift and generous issue of gas-masks and the sudden surprise of balloons over London, all had immediate and heartening effect. Like the symbol of the 'tin hat' or the realization of the tremendous technical resources of the United States behind us, they offer additional justification for confidence.

Confidence further extends to the individual in relation to himself and may then be more properly described as a feeling of *competence*, competence in his own conduct in the enterprise. Self-respect and self-esteem at once improve with the search for the personal share, by the genuine attempt to take up and perform serious and important tasks and in particular by their co-ordination with a common effort. Personal ambition is thus brought into the closest association with comrades and country, strengthened by the conviction of moral rectitude, and is directly linked up with the call of duty. This again reacts to strengthen the sense of responsibility and capability which are enobled by self-approval, encouraging the fullest realization of the self in complete alignment with the realization of society.

The personal side is directly increased by the new feeling of place and position, by news in the exploits of one's own or associated groups, by the exaltation of personal bravery and courage, by the evident approval of public opinion and senior officers, by promotion, real or anticipated, by pride in uniform and equipment, by new surroundings wherein one starts as it were from scratch, by the close feeling of linkage with the nobler episodes of national history, and last but not least by the increased and obvious admiration of the other sex.

All three factors tending to increase morale intimately interact. The increased sense of unity with one's fellow-men, the team-spirit of mutual effort, confidence in the righteousness of our cause and the certainty of the outcome, and the fresh zeal of personal ambition, combine to stimulate a high and ardent spirit in the common man.

Factors Tending to Decrease Morale

Interest in the subject of morale has come sharply to the for elargely by reason of the quantity and quality of the numbers actually involved in the conflict. For practical purposes the exposure to, indeed the frequent reality of bombing, turns everyone into a combatant—worse than that, a combatant deprived of the reasonable outlet of an aggressive reply; this involves a high degree of strain. Besides the quantity, the crude mass of people thrust willy-nilly into this affair, the quality is poor. It is poor in the sense that there has been no calculated preparation for the occasion, none of that assiduous training of both emotion and intellect whereby is created the disciplined unity of the soldier. It is very doubtful if deliberate effort in that direction could be made practicable; more than that it is still more doubtful if it could succeed. The Germans have made attempts by the training of youth and by the distribution of trained agents, but their methods are questionable and their assessment must await future consideration.

Again, the press of warfare fell formerly on a selected portion of the population, selected in age and physique, whose aggressive combative feelings were deliberately led towards an optimum outlet. War took on then for the ordinary adventurous youngster a very satisfactory appeal; it became rather a great game, the greatest of games. But this can no longer describe the situation to-day. 'Total war' has thrust dirty fingers deep into the intimate consciousness of almost every human being, often with a quick sense of acute personal danger. Moreover, it is no longer a short sharp shock calling for gallant bearing, courage and dash; it has become a vehement and prolonged period of tension demanding the deliberate cultivation of a savage resolve.

These are not the days of petty personal vicissitude but of a great upheaval involving directly the selected purposes of humanity. The strain has to be borne by the common man and woman, by loose masses of humanity half developed, half educated, anxious and insecure. Tension so widespread, so severe, so unfair, has brought sharply to the fore visible and unpredictable stresses. It is indeed time to consider and to cultivate morale.

The most important factor tending to reduce morale is a state of *chronic fatigue*. The term is not intended to be used in any restricted sense but is employed to indicate that all-round deterioration of well-being which is brought about by prolonged under-nutrition, by continued insufficiency in the quantity of food and in its quality. Mere bulk of food in no way compensates for a lack of balance and proportion in its components, particularly as regards its freshness. A similar result, though slower in production and less in effect, follows upon long hours of wearisome labour, insufficient or broken sleep, bad housing, bad cooking, bad ventilation. Of these, states of nutrition are the most important for our present purpose. Reference is, of course, intended rather to effects on large masses of the population than in an individual sense, though the latter is more quickly evident and understood.

Adequate, sufficient and satisfactory food is a prime necessity to everyone; a decent meal makes all the difference. Chronic under-nutrition saps the vitality and reduces physical and nervous tone and resistance in a manner akin to prolonged ill-health. It does more; by its appeal to very elementary instincts and needs it creates an urgency tending to override all other considerations. Bread becomes more important than victory; a hungry man will walk up to a machine-gun. Nutrition is further impaired by the other detrimental conditions mentioned. They may be commonplace enough but their incidence is increased in war-time. Their supplementary influence will be readily understood. The consequent ill-effects will be aggravated by psychological conditions encouraging discontent, the blatant evidence of waste, waste in every sense of material and effort, misdirection, reduplication, bad management, personal frictions, distrust and ridicule. But it is probable that the merely physical has the more lasting and more severe effect.

Fear is another important factor causing deterioration of morale. It is related to fatigue, but the former tends to be primary; in states of chronic fatigue fear will the more readily arise, but states of fear do not produce the same fatigue effects.

Conditions responsible for fear in one form or another are, of course, manifold, but there is one the importance of which cannot be over-rated; this is isolation. Under strain and stress swiftly follows an intolerance of solitude, physical or mental. The need of the mere physical contact with our fellow-men is very urgent, and if frustrated or hampered brings about restlessness, impatience and anxiety. While this applies of course to the individual, it plays an important part in the group-mind. The knowledge of friends and allies who are near, able and willing to help, strengthens purpose and confidence by the feeling of support. Isolation, real or apparent, produces or aggravates manifestations of insecurity and impotence, and thereby sensitizes the fear-sense.

Fear has several forms; panic is a "gigantic and senseless dread", apprehension is a continuing anticipation of danger, and fright involves surprise or sudden shock. The effect of mere noise may be here remarked on; this is a primitive fear stimulus, evident in all the preliminaries or actualities of combat from the roar of the lion to the trumpets of a mighty host. The present War is unpleasantly noisy, though the stimulus would not appear to have been deliberately sought by either side. Another point which may be referred to is the production of acute states of fear or shock, the so-called 'shell-shock', and of chronic states of anxiety by continuous recurrence of slighter degrees of very genuine strain against which there is neither defence nor reply.

An index, useful as a rough guide to the extent of fear in a given population, is found in the prevalence of rumour. The stimulus of fear, not necessarily of danger, sensitizes the collective mind, so that an attitude arises swiftly credulous of information reinforcing and fortifying this emotional tone. The degree of fear, more particularly of apprehension, and conversely the degree of confidence, will be reflected in the prevalence or otherwise of rumour. No such situation arises, of course, unless the gravity of the threat be considerable, but that alone does not suffice, a heightening of fear must be added. The same attitude explains the unfounded suspicions of 'fifth column' influences recurrent in a timid, distrustful, over-anxious population. These indicators are worth watching. Apparent lack of progress, even news of serious setbacks, has little or no effect upon a population whose tone is good; for example, the reaction in England to the sinking of two battleships and the loss of an army in Singapore.

Inertia and depression manifest themselves as a result of monotony or inactivity. Just as privations lead to fatigue, and danger, real or imaginary, to fear, so the persistence of long wearisome hours, lack of interest, lack of variety, of change, bad weather conditions, night-work, black-out, home-sickness, distasteful associates, and in particular monotony, monotony which appears to serve no useful purpose, lead to a degradation of moral or physical energy which calls for special remark. There is a loss of sense of proportion, a pre-occupation with oneself, a lack of interest in and capacity for work, a depression of stamina.

Periods of inactivity, complete or partial, when circumstances refuse any reasonable outlet of energy, particularly useful energy, is another form of monotony having similar effect. It is important to recognize that change and variety of occupation and interest represent for human beings a form of rest, physical and mental. The Germans take this point seriously, encouraging frequent holidays and strenuous physical exertion on the part of higher officials.

As in the case of those tending to improve morale, factors of a deteriorating nature may well be multiple and indeed often are. They then tend to exaggerate the respective reactions. States of chronic fatigue from one cause or another clear the ground for fear and depression; conversely, situations likely to produce the latter will aggravate the unpleasant sensations of fatigue.

Conclusion

Morale, more particularly in its national aspects, requires serious attention. The problem in the case of the disciplined soldier is much easier, something concrete has been prepared to work on; it is a very different matter with the shifting unstable masses of a civil population exposed to novel and dangerous stresses. The strain is not merely physical; all sorts of real and imaginary threats hang darkly upon the horizon, stripping away ancient securities and landmarks.

It will not have escaped notice that some, at any rate, of the factors concerned with morale can be directly influenced by deliberate effort, by taking thought. Such effort need not solely derive from authoritative sources but should reasonably come within the province of every responsible person.

Both sides in this Second German War—this Second Punic War—have advantages and disadvantages. The stability and resolution of the Allies may be set against the plasticity and discipline of the Axis peoples. That on the whole the balance would appear to favour the former need not encourage neglect of a factor of increasing, perhaps ultimate, importance.

WILD LIFE IN THE WESTERN HIGHLANDS*

By SETON GORDON, C.B.E.

THE War has little affected the Western Highlands. It has, of course, been in the favour of those animals and birds which are sometimes classed as vermin. But I think that this is a narrow-minded and repellent term, given by those whose lives were formerly devoted to the care (and then the destruction) of the red grouse.

This is the third early summer season that the Highland deerstalker and the Highland gamekeeper have been on 'active service', and the most noticeable result of this absence is the spread of the fox. The fox has now become a menace to crofters and sheep farmers in a number of West Highland districts. More than forty lambs were killed last spring near us in Skye.

The wild cat is also on the increase, although not to the extent that might have been imagined. A deerstalker wrote that he recently found the carcass of a wild cat at a golden eagle's eyrie. There must have been a great fight before the eagle was able to kill the cat—unless indeed the King of Birds had happened to come upon the cat asleep. I have visited many eyries of eagles, but I have never seen a wild cat brought as prey, although I have seen the remains of a stoat more than once. A deerstalker once described to me a tremendous onslaught by a golden eagle upon a wild cat. The eagle swooped on the cat thirty or forty times, with its great talons ready to grasp it. Once, as the eagle came very near, the cat sprang into the air, striking at the eagle with its claws. The spring was so great a one that the stalker saw the whole of the cat for a second suspended in mid-air.

During the month of May, some years ago, my wife and I had a 'hide' at a golden eagle's eyrie on a rock up a lonely glen. We stayed with the stalker in the only house in the glen, and from the stalker's house to the eyrie was a distance of two miles or more. There was a blackbird living near the stalker's lodge. One night my wife had taken an all-night watch in the hide. Eagles sleep very late (for birds) since there is no necessity for them to search for the early worm, and the birds and beasts on which they prey are not usually in evidence until the sun is well up. The blackbird had taken a flight far afield that morning, and before sunrise flew up and perched in the small rowan tree that grew beside the eyrie. Here he began to sing and his song awakened the sleeping eagle on the eyrie. The eagle aroused herself, and glared balefully at the blackbird, which at once flew off to more healthy surroundings.

In the West Highlands is a high cliff where a pair of eagles and a pair of ravens nest. It is astonishing how hard the eagles are mobbed by the ravens, which attack them in the air for half an hour at a time. The ravens have to fly at their topmost speed to keep in touch with the eagle during its downward swoop. The eagles very occasionally turn half-heartedly upon their persecutors, but for the most part treat the attacks with indifference. Only last week I saw this eagle attacked previously by a pair of kestrels. Upon occasion I have seen two eagles attacked in the air by a single raven. Golden eagles do not often nest on cliffs beside the sea. I have seen one eyrie in this site, and the ground at the head of the cliff was honeycombed with rabbit burrows, so that the eagles had not far to fly for food for the two eaglets in the eyrie.

Near that eagle's eyrie is a colony of fulmar petrels. In the British Isles the fulmar is increasing to a remarkable extent. In the year 1878 there was only one colony in Britain, and that was on distant St. Kilda, an island group lying some fifty miles west of the Outer Hebrides. Whether the surplus stock originated on St. Kilda itself it is impossible to say, but at the present day the fulmar nests along the coast of Sutherland and Wester Ross; it has established colonies upon Skye and the Outer Hebrides; upon Mull and the small islands lying to the west of Mull. From Mull, or perhaps from Barra Head, it has spread to

---

[*] Substance of a lecture at the Royal Institution on May 29.

Eire, Wales, and even the coast of Cornwall. On the east side of Britain it has spread from the coast of Caithness, by way of Berwick, to Northumberland, and even to Yorkshire beyond. When it is realized that the fulmar lays only one egg in a season, and may not even lay each year, this increase is one of the most remarkable things in the history of British birds.

The common bumble bee is found throughout the West Highlands. It is a strong flier, and I have met with it crossing the summits of the Cuillin range in Skye. From personal observations I know that there is a flight-line of these bees between the mainland and the Isle of Skye across the Sound of Sleat, a distance of some five miles. From observations I believe there is also a flight line, in fine, calm weather, from Hunish, the most northerly point of Skye, across to Lewis, a distance of some twenty miles. Bumble bees are strong fliers and I remember only on one occasion seeing them defeated by the power of the wind. I was crossing a long line of cliffs in northern Skye and although the sun still shone the south-east wind was increasing to gale force. The wind struck the cliff, which threw the body of fast-moving air high into the sky. This proved an impassable barrier to the bees. Again and again they essayed to fly out over the cliff, and each time were tossed high into the air and swept back, to fall on the heather in the zone of relative quiet behind the cliff. Here bumble bees were to be seen crawling, exhausted, on the ground. The season was September, when the nights are long and cold, and I often wondered what the fate of these storm-beset bumble bees was.

WHAT THE PLANT DOES WITH ITS MATERIALS*

By DR. HUGH NICOL

Imperial Bureau of Soil Science, Harpenden, Herts.

PLANTS build up a large variety of organic substances. The aromatic compounds of plants include several anthracene derivatives, such as the principles of madder and of senna, but scarcely any naphthalene compounds are known: vitamin K is one of these. Most of the organic constituents of plants are formed of carbon, hydrogen, oxygen, nitrogen, and occasionally phosphorus, sulphur and selenium. No organic halogen compounds have been found in the higher plants; there is no sound evidence that iodine or bromine is necessary for plants, nor is chlorine apparently essential.

In plants few types of organo-metallic derivatives have been extensively investigated; of these, chlorophyll is the best known. Phosphorus occurs in organic combination in phytin and some other substances. Calcium occurs as pectate and organically bound in agar, yet, generally speaking, the bases are best known in combination with simple organic acids. Iron is essential for plant growth, but beyond saying that it is indispensable for the production of chlorophyll, into the composition of which it does not enter, there is not much that can be said about its role in the plant; nor, except about a very few elements, can much be said regarding the combinations of elements in plants or about the function of their compounds.

Plants have been shown to require, for their proper development, minute amounts of what the agronomist calls 'trace' or 'minor' elements, meaning thereby elements which until recently were not regarded as necessary, or were even regarded as toxic. The list of necessary elements is now long and is growing. The success of grain formation in cereals grown on some copper-deficient soils of Australia depends upon the uptake by the plants of a few grams of copper per acre. Water from a copper still usually contains enough copper to be toxic if the water is employed for solution cultures; the essentiality of copper is thus a matter of micrograms rather than of milligrams per plant.

The discovery of boron as an essential element for many plants originated in the circumstance that at Rothamsted Experimental Station there was an entomologist who wished to make bean plants distasteful to the black 'fly' (aphis) which he was studying. The Botany Department supplied him with some formulæ for water-culture solutions to include several unusual elements of which boron was one. All his plants died except those which had been given boron. This was in 1921. The matter was looked into, and in 1923 Dr. Katherine Warington published the proof of the need of the broad bean for boron[1]. It is not given to everyone to found a minor industry with her first piece of research, yet this, in effect, happened in her case. Not only has the agricultural consumption of boron compounds attained considerable dimensions but also the importance of salts of copper, manganese, zinc and other elements as manurial constituents is increasing.

The necessity of zinc for pecan trees on the copper-deficient soils of Florida was discovered owing to a copper solution having been made in a galvanized bucket; only trees treated with this solution (which unintentionally contained zinc) responded[2]. An interesting effect of minor elements was also reported from Florida, where orange trees treated with minor elements in addition to the usual fertilizers suffered much less frost damage than did those receiving customary manuring. This offers an example of the dependence of 'condition' upon nutrition. Some minor elements are important for animals though not essential for the herbage plants, which function simply as vehicles. The uptake of cobalt offers an outstanding example of dependence of animals on the soil via the plant.

Plants can be selective in their uptake of elements. There is geochemical interest in the concentration of mesothorium by a pond plant[3]. From the point of view of essentiality and uptake, one of the most interesting elements is selenium. Its physiological role has been recognized only in the last decade, owing to the investigation of seleniferous soils. These soils have only a small selenium content, but cover vast areas in North America. Marco Polo recorded poisoning of animals in China which has since been shown to be referable to a seleniferous soil. A similar condition in Ireland remains unexplained[4].

In their reactions to selenium, plants can be divided into four groups: those which require selenium, those which can tolerate large amounts in their tissues, those which can tolerate small amounts but are poisoned by large amounts (these include crop plants such as wheat), and those which practically exclude it. The last group comprises some native prairie grasses. The first group is formed by some species of the botanically varied genera Astragalus, Oonopsis and Stanleya; for these selenium is an essential element, and the concentration in the dry matter and in the seed may surpass 3,000 parts per million. Recently an amino-acid complex containing both selenium and sulphur has been isolated from grain and from Astragalus[5].

---

* Substance of a lecture given before the London and South-Eastern Counties Section of the Institute of Chemistry, at the Institute on April 15.

Plants for which selenium is essential, such as certain species of Astragalus, will, of course, grow naturally only on seleniferous soils (the converse does not hold). Hence they serve as an interesting introduction to the subject of 'indicator' plants—that is, plants which by their presence or mode of growth indicate soil conditions. The medieval discovery of alum in Italy and the establishment of its manufacture as a Papal monopoly are said to have originated in the finding at Tolfa of a plant supposed to be the same as one which grew near the older alum mines of Asia Minor[6].

The plant's raw materials are all very simple chemically; unlike the animal, the plant is not adapted for the assimilation or digestion of complex foodstuffs, and if complex materials are presented to the plant they must first be broken down by bacterial or other action before the plant can take them in. The chief rôle of the soil is to serve as the nidus for such decompositions: weathering for the breakdown of minerals, biological decomposition for the breakdown of plant remains and other organic matter. An important product of decomposition both in the soil and in the tissues of living organisms is carbon dioxide. The only recognized sources of carbon dioxide and indeed of carbon for the plant are the atmospheres above and in the soil.

Pliny referred to the product of respiration as *spiritus letalis*, but it would be truer to call carbon dioxide *spiritus vitalis*. The application of radioactive tracer carbon has shown that reduction of carbon dioxide is a general property common to all living cells, and has led to revolutionary ideas regarding the mechanism of the photosynthesis of sugars in the insolated plant. The initial step in the assimilation of carbon dioxide by photosynthesizing cells is a dark process independent of light. The first intermediate in photosynthesis has been isolated and has been partially characterized as a large molecule of molecular weight about 1,000, having a free carboxyl group and an alpha hydroxyl group. This is supposed to be an enzyme or a prosthetic group of an enzyme and it reacts like this:

$$\mathrm{RH} + \mathrm{CO_2} = \mathrm{R\,COOH}: \text{ dark reaction,}$$

in which RH is the reduced enzyme group. The light reaction or photochemical step then occurs:

$$\mathrm{R\,COOH} + \mathrm{H_2O} \xrightarrow{\text{chlorophyll}} \mathrm{R\,CH_2OH} + \mathrm{O_2}$$

$\mathrm{R\,CH_2OH}$ adds another $\mathrm{CO_2}$ and the process is repeated to build up long carbohydrate chains[7]. Green plant photosynthesis is only a special case of the general biological phenomenon of dark carbon dioxide reduction.

All plants, even those inhabiting arid regions, are very wasteful of water. For every ton of grain or of dry matter produced, several hundred tons of water are passed through the plant and are discharged as vapour into the atmosphere. The remaining elements are mainly assimilated through the roots, though some for which the plant has only a small requirement can be absorbed through the leaves and stems. Plants are ionic feeders, and they need their ions as simple as possible.

That the plant is not a homogeneous absorbing system is shown by experiments with roots divided between nutrient solutions of differing composition, whereby corresponding differences are produced in the tops. Dr. John Caldwell has suggested that plants having decussate phyllotaxis lend themselves to neat demonstrations of this inhomogeneity, as when half the flowers of a hydrangea plant were red and the other half blue.

Asymmetry in absorption is well shown by the observation that swedes in the field develop better on the south side than on the north. Here are some averages, after Caldwell[8].

TABLE 1

RADII IN MILLIMETRES, OF QUADRANTS OF SWEDES

Rows running	N	S	E	W
E–W	49·5	58·5	50·9	59·5
N–S	44·5	50·8	46·5	49·5

This is due to differential assimilation by variously insolated leaves.

Intake of nutrients through roots takes place in three ways: direct absorption of anions and cations through the finer roots and root hairs; absorption or exchange of nitrogenous compounds from nodules attached to the roots of many leguminous plants; indirect absorption through the medium of fungi which together with the roots form what are known as mycorrhizæ. Recent knowledge about roots has given new perceptions about their extent[9]. T. K. Pavlychenko has measured the roots of single prairie grasses grown free from competition of other plants and has recorded more than three hundred miles of root belonging to a single plant three years old, while a single plant eighty days old had fifty-four miles of roots of first and second order alone. A young plant may have a net gain of the order of one mile of root daily. Roots are neither permanent, as a rule, nor static. The finer roots of a living plant are constantly being shed, and thus are taking part in the cycle of decomposition in the soil. W. S. Rogers[10] has demonstrated the impermanence of roots of such a substantial plant as an apple tree. Within a few weeks apple rootlets have been observed to grow and decay, fresh ones being formed meanwhile in the same region of soil.

There is a balance between the amount of root and the amount of top. By cutting the tops of a plant—say, by mowing the lawn—the roots are also trimmed. (Table 2.)

TABLE 2

DRY MATTER PRODUCTION, IN GRAMS, OF LUCERNE CUT AND NOT CUT[11]

Tops	July 6	July 27	Aug. 24
Unclipped	10·4	17·7	20·4
Clipped once, July 5		18·5	
Clipped twice, July 5 and 26		(clippings	24·5 included)
Roots			
Unclipped	5·8	16·5	24·1
Tops clipped once		10·3	
Tops clipped twice			16·0

A closely cut lawn suffers during a drought because the diminished roots are not able to reach the soil moisture in the deeper layers.

Roots are not merely absorbing organs; they are also reserve organs. The relation between tops and roots has important practical consequences, since if perennial forage plants and grasses are cut or grazed too closely in late autumn they will not be in a good condition to survive the winter or to make early growth in spring, on account of the lack of sufficient reserves in the roots. Nitrogenous manures applied in spring are no substitute for adequate over-wintering root reserves.

Leguminous plants may possibly excrete nitrogen fixed by the aid of their associated nodule bacteria, and may thus act as nitrogen 'foster-mothers'. The dynamics of the plant include several modes of return of absorbed material to the soil. The most obvious in perennial plants is leaf-fall.

A more interesting mode of return of nutrients to the soil is apparently common to annuals and perennials. It is what the Rumanian worker N. T. Deleanu has called *Rückwanderung*. The demonstration of this process is not very simple with modern data, but the work of J. I. Pierre in the 'sixties is of interest[13]. Table 3 shows amounts of some elements present in the whole wheat plant.

TABLE 3

KILOGRAMS OF CONSTITUENTS IN A HECTARE OF WHEAT (WHOLE PLANT INCLUDING ROOTS). (AFTER J. I. PIERRE, 1863.)

	June 13	June 29	July 13	July 30 (harvest)
Total organic matter	5400	6500	6900	6800
N	76	76	68	70
SiO_2	191	252	214	228
Fe_2O_3 -	15	30	17	19
CaO	44	45	44	36
K_2O	39	55	34	34
P_2O_5	18	19	18	23
,, in ears	2	4	7	17

There is a maximum of richness a month before harvest; the only constituent that goes on increasing is phosphorus in the ear. While possibly some of the potassium is washed out by rain, it seems that part of the early stock of nutrients has been returned to the soil. Plants can absorb ions from true solution, but the soil solution theory is unable to account for *Rückwanderung* or for what has been called contact depletion.

The ideal soil is not composed of discrete mineral grains, but of crumbs or aggregates. These include colloidal matter of two kinds—mineral colloids and organic colloids. The latter may be partly humus, which may be regarded as an *end-product* of the microbial decomposition of organic matter. In a fertile soil the organic matter includes a sticky material less inert than humus, and resulting from the recent decomposition of organic matter[13]. This organic cement sticks the grains together into small crumbs which have the most desirable physical properties. It is not the microbes which are important in soil, but the products of their recent activity are important.

There is reason to believe that the plant and the soil with which it is in contact form a practical continuum. This contention gains weight from the work by H. Jenny and R. Overstreet on ionic exchange. If plants are grown in mixtures of sand and calcium clay, the roots accumulate calcium ions, whereas the clay particles gain in adsorbed hydrogen ions. Contact exchange is postulated to take place only when the (cation) oscillation spaces of particles overlap: the particles may be both clay, or one may be a root surface, both being negatively charged. Contact intake is difficult to investigate on account of a presumed high gradient of carbon dioxide in the neighbourhood of a root, but there is very suggestive evidence of contact depletion, so that the theory of contact exchange of ions may be regarded as having made a promising beginning. There is yet no evidence for contact exchange of anions. No contact jumping of cations could be found between roots and positive iron hydroxide sol[14].

The disposition of materials by plants is a highly dynamic and largely cyclic set of processes. There are, of course, wheels-within-wheels: short-period cycles as well as long-period cycles. The broad cyclicity of nutrients is well shown in the tropical rain forests, where most of the nutrient stock remains, and the greater part of the nutrient cycle takes place, *above* the ground. In cool humid climates the cycle is impeded, and valueless plants such as heather constitute the type vegetation. The ideal agricultural soil is one in which the cycle is fairly shared between soil and plant. Artificial modifications in pursuit of the full roundedness of the soil/plant cycle are the purpose of man's operations in cultivation and manuring.

AD ASTRA*

By THE RIGHT HON. LORD BRABAZON, P.C.

I THINK I am speaking the truth when I say that those who were responsible for the birth of flight thought of it as a new force in the world for peace, for prosperity and for true internationalism. Here was to come something which would make the world a happier place by a quick form of transport, that would bring us all closer together. It was for that idea that I saw my friends pour out their meagre fortunes in experiment, and risk their splendid lives in brave endeavour. I contend that the crushed, shapeless or charred embers of so many victims were well sacrificed, if they were to bring about such ideals. But mechanical science outstrips human wisdom, until we find we have created a juggernaut that may indeed destroy us. I want it clearly realized that if to-day flight bears the brand of Cain, it is not on the pioneers that the blame should be laid, but on foolish politicians of many countries.

Holt Thomas must bear an honoured name in trying to use war aircraft for civil purposes, with resultant commercial disaster. The Government stepped in with half-hearted support to an enterprise which meant so much to a far-flung Empire, but so lacking was vision that the only thing ever indulged in was puny assistance to civil aviation and, on the military side, the provision of a few squadrons of aircraft, always at least seven years out of date.

---

* Part of the Wilbur Wright Memorial Lecture for 1942 of the Royal Aeronautical Society, delivered on May 28.

The while Governments were striving after war machines it was left to keen competition in civil aviation in the United States to bring about the first real advance in civil flying. The Douglas is so well known as not to warrant description, but it did promise that at long last the civil side of flying was to go along a separate path in development, and would become divorced from military development. It was later found that as a military bomber the commercial machine was superior to all Government-produced machines.

It has been said by many, and there is much truth in it, that it would be better for us to win the War first before we think and plan for post-war situations. This is one of those half-truths that are so very dangerous, leading one really astray.

The Germans are fighting for a post-war position. We are fighting to resist the imposition upon us and others of an intolerable post-war bondage. Surely, therefore, we both have in our minds the whole time a post-war position. If that is so, there is nothing to be ashamed about or to find deplorable in supposing victory, and to allow one's mind to browse over some of the ameliorations that we should like to see introduced into our beloved country.

The early struggles of flight had not got very far when there came the War of 1914–18. Into that effort there was a tremendous concentration on aviation. For the first time all the efforts of engineers and other men of science were concentrated on the subject with, moreover, unlimited money behind it. It was a mushroom growth not entirely on healthy lines. Field of fire, manœuvrability, lack of blind spots, rate of climb were all points of first importance. Such things as pay load, initial expense, inherent stability, economy of fuel consumption, lack of danger from fire: all those really basic matters that would have come into normal development of a new form of transport were passed by and we were left at the end with certainly a very wonderful advance, but one upon which debate may still rage as to whether the quick growth really helped the science along or retarded it.

I have said that Holt Thomas, trying to use war machines for civil purposes, found that it was an impossibility, so detached from an economic machine had the aeroplane become. Many of us hoped and prayed that a very real divergence would come about between the military type and the civil type. This was not to be, however, anywhere except in the United States, where free competition developed in a country of astronomical distances, which was made for flying development.

All Governments, almost without exception, put their hands upon the aeroplane and said that the State would do this and not allow that. They always saw through a sort of fog also that they must regretfully have at their disposal a nucleus of private firms making aircraft against the necessity of another war.

Civil aviation was born too soon from the bowels of the War of 1914–18 and was mis-shapen from the start, so that it could not, until completely reorganized from a design point of view, *fly by itself*. A vicious circle ensued, therefore, wherein firms wanted to make a civil machine, but as air transport could not pay there were no buyers, and as they had to keep alive they continued making machines that were suitable for war purposes only. Slowly the industry became the tools of the air bureaucracy of their country, who dictated to them what to make. With a lip service to disarmament, actually to keep alive an industry for war, State subsidies started up and down the world nominally to keep flying services going. Take the case, just as an example, of engine development. In all other forms of transport the C.I. or Diesel engine has displaced the petrol engine, for economy in the case of ships and for the buses of London. Notice it was adopted here not entirely for reasons of safety. But in an aeroplane the safety reason was of paramount importance. The statement that I have had given to me, that fire did not matter as most people were killed before they were burnt, is a travesty of the truth, as an aeroplane is never in more danger than when it is not going very fast and is in contact with the ground. Yet did a C.I. engine emerge? No. For this reason: Governments were not interested in it, as it showed no great advantage for war and therefore the manufacturer had no market in which to sell his product if the State-run air-service was not going to encourage such a thing.

Thus history shows that the birth of flight was of clean parents; but due to the War of 1914–18 it was branded with the mark of Cain and ever since it has been tied to the apron strings of Mars. It is a sorry story, and although here and there I and others can point to some cases of honourable endeavour to get away from the position I have described, I think that most fair-minded people will agree that what I have said is the truth.

Is there to be such lack of imagination, such supineness, shown in the world again? I feel it only right that we should consider this problem while we are under stress and strife, and plan and arrange the future. Otherwise I know that it will pass to a tired and poor post-war world with little energy or imagination, only wanting to be left alone to lick its wounds.

I take it first of all as axiomatic that those nations that have fought together and suffered together, and won together, are going to remain friends and work together. What is curious, however, is that most of these nations are, above all, nations that are concerned with very long distances as the basis of communication. I suggest that the United States, the U.S.S.R. and the British Commonwealth, with the United Nations, should announce that henceforth they jointly and solely take charge of all aircraft and all flying, that the *Usque ad Cœlum* (ownership of air above any particular piece of ground) doctrine goes and that in future they give themselves the right to fly whithersoever they like, and that no one anywhere on earth shall fly without their consent. Thus there will be a watching force to see that nowhere in the world shall a nation secretly build up an air force for mischief. This combination will be the start of a Kipling's "A.B.C." It would, of course, delegate to countries their own internal organization for local flying, but always under its broad control. But the great long-distance highways will be in their charge and run by international crews. They will at first operate war machines for intercommunication until better are made by the industry existing, which cannot be dissolved overnight. In return for taking upon itself these great powers, the World Board will guarantee all States against aggression and will constitute to itself the policing of the world. Where we make a difference from the League of Nations idea is that here we will be creating, right at the beginning, a force of transcending power that no one can challenge, instead of a debating chamber that had no force at its command. I do not for one moment lay it down that at the right time our present enemies should not come into the general scheme. The idea is world co-operation and not penalization. It is high time with the resources at our command that we protected ourselves against a world war every generation. Here in our hands we have the instrument so to do.

A world-wide development of civil flying would have great repercussions on human life and materially improve the standard of living. The exploitation of this great invention to be put to the use of man rather than his destruction is long overdue. The world shrinks in size as time separation diminishes. Mails and passengers would be the first to be served, movement of heavy goods for some time remaining in the hands of the older systems of transportation. What the world holds for us in tariff barriers in the future we do not know, but it is to be hoped that an easier, freer circulation of travellers to and from all countries will be encouraged rather than at present frowned upon by a narrow spirit of nationalism. There are also great tracts of land, rich and climatically possible, waiting to provide a happy life for many, who at present due to lack of communications cannot live there with their kith and kin. With flight our servant, there should be no corner of the earth not readily accessible.

You may say this is post-war planning with a vengeance. To which I reply that there is no one fighting on any front who has not in his heart the idea of a fairer world afterwards where his children and for a time he himself can go about his lawful occasions.

We in Great Britain have seen a revolution take place peacefully in our land over the last twenty years. There is much more to be done. But no amount of planning of our lives and our social progress can be of value or be permanent unless we see clearly and appreciate the potential danger that man has created through the conquest of the air, and so organize the future that it is no longer a threat, but becomes the servant of man. To finish the job we have in hand and then to drift into a fools' paradise would be a tragedy little worthy of the efforts we have made to remain masters of our own destiny.

NEWS and VIEWS

Colonial Policy

MR. HAROLD MACMILLAN, Parliamentary Under-Secretary of State for the Colonies, gave an informative account of the activities and plans of the Colonial Office, in moving the vote for that Office in the House of Commons on June 24. Dealing with the present, Mr. Macmillan said the Allied losses in the Far East mean an immediate and important loss of supplies; 60 per cent of the tin production of the world, 90 per cent of the rubber production, a large proportion of the wolfram and lead, and valuable sources of sugar, tea, rice and oil seeds have fallen to the enemy. Making good the deficiencies will mean an immense increase in Colonial production. In an endeavour to bridge the gap which must occur before large-scale production of synthetic rubber in the United States can be effected, the rubber output of Ceylon has been intensified, the services of Malayan planters have been obtained to assist in reviving plantations in Tanganyika, and wild rubber in East and West Africa is being tapped. Mineral production in the Colonies is being stimulated. The Colonies are also contributing notably to the war effort by decreasing their imports. West Africa is concentrating on the production of rice, vegetables and dairy produce; East Africa is increasing its production of wheat, maize, rye and other foodstuffs. In the West Indies an attempt is being made to introduce more and diverse food crops.

Mr. Macmillan went on to speak of the future. The governing principle of the British Empire must be partnership, he said, and there must be room for the greatest divergence of local responsibility. We must begin now to prepare for changes in the organization of the Colonial Service, with two main objects. First, the civil services and the educational systems of the several Colonies must be so devised that the people are able to qualify for, and desire to serve in, the public services of their own countries. Help would still be needed from outside, however, and this could be provided by a mobile force of experts in administration, medicine, agriculture, finance, etc., at the disposal of the Secretary of State for posting to whatever Colony they are needed at a given time. In this way the present anomaly of the poorer Colonies not being able to obtain the services of the best brains—of which they are actually in greater need than the more advanced and wealthier Colonies—would be removed. Plans are being worked out to achieve this end.

As regards questions of labour and development, Mr. Macmillan remarked that six experienced trade unionists from Great Britain have recently been appointed as Colonial labour officers to British Guiana, Trinidad, Nigeria, the Gold Coast, Sierra Leone and Palestine, to stimulate the growth of trade unionism; and twelve officers from the Ministry of Labour have been seconded for service in local labour departments. Lord Hailey, with the help of eminent men of science, will advise on the organization of research, for which £500,000 a year will be available, on health, nutrition, education, etc., and also on practical economic needs. The Colonial Development and Welfare Act provides for long-term planning, which must be used to assist the Colonies to reach present-day standards of life in the shortest possible time.

THE membership of the Colonial Research Committee referred to by Mr. Macmillan has since been announced. It is as follows: Lord Hailey (chairman); Sir Edward Appleton, secretary of the Department of Scientific and Industrial Research; Prof. A. V. Hill, secretary of the Royal Society; Sir Edward Mellanby, secretary of the Medical Research Council; and Prof. W. C. C. Topley, secretary of the Agricultural Research Council.

Part-time Employment

A PAPER on "Part-time Employment" read before the Royal Society of Arts on June 10 by F. C. Hooper, joint managing director of Messrs. Lewis's, Ltd., describes the inception and working of the part-time scheme of that firm. The details of the scheme were worked out in July and after submission to the Ministry of Labour the scheme was launched by advertisement on August 18. The appeal was addressed to married women of thirty-five and more to avoid the problem of married women with very young children, and particularly with a view to the rapid release of younger women. Mr. Hooper lays considerable stress on the patriotic appeal, sufficiently so to raise the question as to whether it is right to allow non-industrial industry to utilize part-time labour in this way unless it can be demonstrated that all munition and other essential industrial demands for labour have been fully met. Apart from this the paper lays down a number of principles which are clearly of value in launching any such scheme and which go far to determine success. The regular character of the job and that it is for a fixed time during the day or fixed days during the week, as well as the importance of regularity in time and attendance are impressed on all applicants, and few applicants failed to fit themselves into one or other of the schemes scheduled by Messrs. Lewis's, Ltd. Firm handling of this problem, Mr. Hooper said, has reduced bad time-keeping and absenteeism to a minimum. Much stress is also put on proper welfare arrangements and adequate training, and on the importance of utilizing all the usual means for getting the new employees over the early and most difficult stages of their employment. Accordingly, although a fairly large proportion of the first applicants were lost, fewer really unsuitable applicants are coming forward. Moreover, the firm has been surprised at the comparative ease with which part-time workers have fitted into their administration and at the quality of the part-time workers themselves, the average age of whom was about forty-five.

In addition to the stress on the importance of welfare and personnel work, for which a member of the Board has always been responsible, there is in each business a staff manager with high administrative authority and strictly commercial responsibility, with both a Welfare Department and a Staff Training Department. Mr. Hooper also stressed the extreme importance of explaining the scheme in advance to the management and full-time staff and of securing their co-operation and sympathy. As a result of this handling of the psychological difficulties and the putting out of clear instructions rather than appeals, in no section has there been any real difficulty in employing part-time workers. Two main methods were used. Where work requires verification and constant reference, a team of two or four part-timers work in association with one full-timer. In specialized office work wherever possible part-time workers take individual responsibility for their particular work, the size of self-balancing ledgers and salary books, for example, being reduced so that the workers can complete their work during the shortened hours. This usually works better than a team of two, one morning and one afternoon, being conducive to individual pride in one's work and avoiding the tendency for one half of the team blaming the other for mistakes. All the privileges of the regular staff are accorded to the part-time workers, who are expected to observe the same standard of discipline; the use of the term 'auxiliary' for the part-time staff has also promoted friendly relations and appealed to the patriotism of both.

Drying Blood Plasma and Blood Serum

THE Trustees of the late Sir Henry S. Wellcome have generously placed a sum of up to £20,000 at the disposal of the Medical Research Council for the purposes of research into methods of drying blood plasma and blood serum to provide stable products for use in the transfusion of patients suffering from hæmorrhage, shock, or other conditions requiring such treatment. By agreement between the Trustees and the Council, this gift is to be applied to the purchase, erection and operation by the Council of a plant which will make it possible to test and develop these methods on a substantial scale. The need for the improvement of such methods is of particular importance at the present time, and the products will be made freely available for the treatment of sick and wounded at home, at sea and abroad. The Medical Research Council has expressed its appreciation of this timely and public-spirited action on the part of the Wellcome Trustees.

Dr. Aleš Hrdlička

THE retirement of Dr. Aleš Hrdlička from the curatorship of the Division of Physical Anthropology in the National Museum, Washington, which he has held for almost forty years, is an event which no scientific journal can leave unnoted. Under him there has grown up in the National Museum one of the greatest—if not the greatest—collections of anthropological material in all the world; he is founder and leader of the enterprising school of physical anthropology which now flourishes in the United States. Born in Czechoslovakia in 1869, he was still a youth when his family emigrated to the United States; there he became a student of medicine and it was through the medical portal he entered upon the anthropological problems of the human body. On the anniversary of his seventieth birthday a list of his contributions to anthropology was compiled; they are now more than three hundred in number, covering every aspect of his subject, every one of them making a factual addition to a particular department of knowledge.

Dr. Hrdlička is beyond doubt the most travelled anthropologist of his time; there is no part of the world he has not visited in search of material and of knowledge. He made the circuit of the world several times to examine and report on the fossil remains of early man. His reports, issued from time to time in the publications of the Smithsonian Institution, are recognized throughout the world as the most reliable sources of fact relating to the discoveries of fossil man. His studies on the Old Americans (men and women of British ancestry), of the American Indians and of the Negro population of the United States have become classics. He has sought to trace the first peopling of the New World from a Mongolian homeland in north-east Asia and has explored Alaska for evidence of early migrations. In Alaska, too, he has dug up cemeteries attached to older Eskimo settlements; he has added greatly to our knowledge of the Eskimo, both ancient and modern. Dr. Hrdlička made warm friends wherever he went, particularly in England. He lectured in London in 1939 while on his way to the U.S.S.R. to examine the various finds of fossil man which have been made there in recent years. In 1926 his Czech colleagues issued a "Hrdlička" number of *Anthropologio* in honour of their distinguished countryman. At the close of the War of 1914–18 he founded the *American Journal of Physical Anthropology*, now the leading publication of its kind.

New Zealand Earthquakes

A STRONG earthquake shook a considerable area in New Zealand at about 11.18 p.m. (local time) on June 24. The places most affected were Masterton, Eketahuna, Greytown and Carterton. Property in Wellington and Palmerston North was damaged. At the southern end of the North Island, therefore, extensive minor damage was done over a wide area, windows being broken, chimneys dislodged and so forth, though no casualties have been reported. Buildings erected since 1933 under the earthquake by-laws (similar to those in force in many parts of California), have suffered only superficial damage. The main shock was preceded by a precursor shock at 8.15 p.m. (local time). The principal shock is said to have been the most severe since February 1931, when more than two hundred people were killed in the Hawke's Bay region as the result of a very severe earthquake. New Zealand is a seismic region, and hundreds of minor shocks occur every year. The study of these, and the multitude of seismological problems which arise, is actively pursued at Wellington, and we await further news of the present shock from the Dominion Observatory.

During March 1942, nine distant earthquakes were registered by the seismographs at Wellington, Auckland, Christchurch and Arapuni in New Zealand, according to the seismological bulletin just received from the Dominion Observatory, Wellington. The greatest appears to have been on March 5, when the ground movement at Wellington was 3 mm. downwards, and the shock is estimated to have had its epicentre some 82° from Wellington with a focus rather deeper than normal. The shock was recorded at Wellington at 20h. 00m. 51s. U.T. Microseisms interfered with the registration and the interpretation of the records throughout the month.

Additionally, 21 local earthquakes were recorded. The greatest was of intensity 6 on the Rossi-Forel scale (ringing of bells, stopping of clocks, visible disturbance of trees and shrubs, etc.), which occurred on March 25 at 15h. 49·6m. U.T. and was felt at Milford Sound and Queenstown. Six subsequent shocks were felt in the same area though they were of lesser intensity. Other areas affected by earthquake activity were Opotiki (March 2), Motu (March 3 and 5), Pipiriki and Whangamomona (March 5, 6, 10, 12, 16 and 18), Napier and Hastings (March 20), and Te Whaiti and Taupo (March 22). Focal depths of these local earthquakes have been estimated to range from normal (about 16 km.) to 100 km. The bulletin is stated to be provisional, but it contains much useful data.

Colour of Machines and Workshop Efficiency

UNDER the title "Color for Efficiency", Matt Denning and Arthur A. Brainerd have described experiments made in an American machine shop by re-painting the machines in pale colours (*Product Engineering*, Jan., 1942). Machines are usually painted black or battleship grey, and their surfaces thus have a low reflexion factor. There is often too little brightness of colour contrast between the work and parts of machines forming its background. If these parts are finished with light-coloured paint, contrast is improved, and the work made easier to see. Moreover, the illumination of the work itself may be improved by light reflected from machine surfaces. The whole machine may be painted a uniform colour, or a different, but also pale, colour can be used for parts not in close proximity to the work. The general brightness of a machine shop is enhanced by this treatment. Where high machines, such as heavy presses, are used, a high reflectivity of their superstructure means that more light is reflected to adjacent machines, and troublesome shadows may be avoided. The colours tested were ranked on the results of a work-time study and on opinions of machine operators and measurements of reflexion factors. Light buff proved best, then aluminium and light grey. Yellow was found to be tiring. In Great Britain, the advantages of painting machines a light colour were recognized by the Departmental Committee on Factory Lighting, which recommended this practice in its fifth report, published in 1940; recent trials here have proved very satisfactory.

Hormone Sprays for Fruit

THE recent rapid developments in the investigation of growth-promoting substances have been closely followed by widespread attempts to apply the so-called plant hormones in horticultural practice. The use of synthetic growth substances to facilitate the rooting of cuttings became a craze almost overnight, and there is no doubt that remarkable results were achieved in many cases. There are still, however, species which resist all attempts to make them produce roots readily enough to make this method of propagation practicable on a commercial scale.

Other uses for growth substances have now become the centre of interest, and these form the subject of a review in the *American Fruit Grower* of June 1941. Perhaps the most successful application has been the use of naphthalene acetic acid and naphthalene acetamide to control the pre-harvest drop of apples. Spraying with dilute solutions of these substances, by delaying the formation of the abscission layer, enables fruits to be kept on the tree until a desirable degree of colour and maturity is reached. Fruit dropping from pears, plums, apricots, oranges and cherries has also been reduced, and, in the case of the latter, the sprayed fruits showed a lower acid and higher sugar content than the controls. Satisfactory results with some English varieties of apple have been obtained by similar methods at the East Malling and Long Ashton Research Stations. The method appears to be of particular value in combating the effects of strong winds. Also of interest is the checking of bud development by hormone sprays. By this means the risk of frost injury to fruit blossoms in spring may be reduced. Indole butyric acid, applied unilaterally to growing shoots of young apple trees, causes more rapid growth on the treated side. By this means the development of narrow-angled and therefore structurally weak crotches can be avoided.

Porcelain Insulators

WRITING in the *Electrical Review* of June 12, 1942, on the design of electrical insulators in relation to manufacturing processes, Dr. E. Rosenthal points out that methods of shaping ceramic materials are based on the plastic quality of the china clay and ball clay in the case of porcelain, and of clay, talcum or bentonite in the case of certain ceramics. The plasticity of ceramic materials is caused by the adsorption of water at the surface of the kaolinite crystals forming the china and ball clays, this water surrounding the clay molecule. The forces which attract the water to the molecules and crystals are electrical in origin and impart to the clay molecules their colloidal and plastic nature. The hygroscopic water and the "water of formation" form the colloidal gels which give to the clay particles their plastic characteristics. All ceramic plastic materials also contain chemically combined water of crystallization. Although ceramic articles can easily be shaped as a result of the plasticity of their raw materials, the finished materials owe their physical and mechanical properties to the crystals and to the glass matrix formed during firing at high temperatures.

In contradistinction to ceramic plastic raw materials, the plasticity of organic plastics is not caused by water but by the long chains of carbon atoms or arrangements of carbon atoms with other elements of which their molecules consist. These chains are arranged in various forms, such as long bundles or micelles and in tangled masses composed of threads. During manufacture plastic organic materials are transformed by heat (or by heat and pressure) into a non-plastic state, nothing being evaporated. Only the structure of the big molecules is altered and as only very small shrinkage occurs greater accuracy in certain shapes can be obtained from organic-plastic than from ceramic materials. Incidentally, the molecules of ceramic plastics are built up of silicon compounds, whereas those of the organic plastics are built up of carbon compounds—an instance of the many similarities of these two elements. With organic plastics, transformation from the plastic to the non-plastic form which gives the materials their mechanical and electrical characteristics takes place at about 180° C. In the case of ceramics the formation of the crystals and the glass matrix, which imparts these characteristics, takes place between 1,300° and 1,400° C.

The difference between the manufacture of ceramic and other materials, such as metal parts and organic plastic materials, is therefore that the article is not shaped from ready-made material but has first to be prepared from various plastic and non-plastic substances. After the water is removed in a filter press the body is homogenized, and out of this body the article is shaped into the desired form which is then dried and glazed and subjected to very high temperatures for final formation. The methods of manufacturing porcelain and low-loss ceramic articles containing talcum are very similar. The article proceeds to a description of the various processes employed in the commercial production of porcelain insulators.

Stellar Structure

A PAPER on stellar structure appears in the *Observatory* of May, in which Dr. T. G. Cowling gives a brief summary of the work of various physicists on the theory of stellar structure during the past ten years. A large portion of the paper is devoted to recent developments in the physical theory of the generation of stellar energy. The work of Gamow, Weiszäcker and Bethe has shown that the most probable mode of generation of energy is by the transmutation of hydrogen into helium, atoms of carbon and nitrogen acting as catalysts in the reaction. Assuming that the temperature at the centre of a star is about 20,000,000° K., increasing temperature implies increasing rate of generation of energy—approximately as the seventeenth power of the temperature—and the popular idea was that instability of the star would ensue. This view is erroneous because the generation of energy does not affect the internal temperature for a period of the order of a million years, and in this time the star can adjust itself so as to dispose of the extra energy.

It has been argued that reaction between energy generation and temperature would produce radial oscillations, such as are observed in the Cepheids, but how can their absence in other stars be explained ? A possible explanation may be found in the time-lag between increase in temperature and the resulting increase in generation. Another explanation given by Cowling is that a very large dissipation of the energy of an oscillation takes place in the outer layers of a star, but this dissipation is so large that it is difficult to understand why Cepheids continue to oscillate. Eddington believes that the dissipation in their outer layers is very low because of the changes in hydrogen ionization during the oscillation. On the whole, therefore, there are no objections on astrophysical grounds to the view that the energy of a star is nearly all generated in the hottest central part. Other matters considered include the Kelvin-Helmholtz hypothesis that stars radiate because gravitational energy is liberated as they contract, and observational evidence regarding the internal state of eclipsing binaries.

The University of London

THE title of professor emeritus of anatomy in the University has been conferred on Prof. J. E. S. Frazer, who resigned from the University professorship of anatomy at St. Mary's Hospital Medical School in March 1940. The title of reader in geography in the University has been conferred on Dr. S. W. Wooldridge, in respect of the post held by him at King's College.

The degree of D.Sc. has been conferred on Prof. R. V. Christie, University professor at St. Bartholomew's Hospital Medical College ; Mr. Frank Dickens, of the Imperial College of Science and Technology ; Mr. Charles Potter, of the Imperial College of Science and Technology ; Mr. E. E. L. Dixon, an external student ; and Mr. C. E. Lucas, an external student.

The University of the Philippines

FEARS were expressed, in the early days of the invasion by the Japanese of the Philippines when the open city of Manila was bombed, that the University and other colleges of the city, some of them of great antiquity, might have been damaged or destroyed. It is therefore welcome news to learn that no damage of any kind has been suffered by the buildings of the University of the Philippines or, apparently, by other educational institutions. The bombing was concentrated on a small area in another part of the city.

Announcements

Archbishop Lord Lang of Lambeth and Sir Charles Sherrington have been elected trustees of the British Museum.

Sir Henry Dale, president of the Royal Society, has been appointed chairman of the Science Committee of the British Council, in succession to the late Sir William Bragg.

Dr. F. W. Hardman and Mr. W. P. D. Stebbing, in two articles in *Archæologia Cantiana* (53 and 54), have outlined the history of Stonar and the Wantsum channel. As the prosperity of the place depended entirely on the state of the channel, this is discussed at some length in the first article. While the matter is primarily of interest to the local antiquary, there are aspects which make it of wider importance.

Metabolic Water and Desiccation

THE utilization by the body of ingested food substances and of tissue reserves yields among other things quantities of metabolic water. As the complete combustion of 100 gm. of fat produces about 110 gm. of metabolic water, whereas 100 gm. of carbohydrate yields only 55 gm. of water, fat reserves and fatty foods are believed to be particularly valuable as a protection against desiccation. This contention would appear to be supported by the fact that many animals which exist in deserts have large reserves of fat.

I believe that the idea that fat is primarily a protection against desiccation is based on fallacies. Terrestrial animals, which have evolved eventually from aquatic forms of life, are always apt to suffer from desiccation, and many well-known mechanisms for water conservation exist. Respiration always presents a difficulty, and a serious loss of water often takes place from the surface of respiratory organs. The more a terrestrial animal takes in oxygen, during respiration, for its metabolism, the more water there will be lost in the (practically saturated) expired air; this is equally true of insects and mammals. In man, the water lost from the lungs is generally greater than the total production of metabolic water. When desiccation is the limiting factor (and animals usually die from lack of water long before their food reserves are exhausted) the significant figure is not the amount of metabolic water produced for unit consumption of any reserve, but the amount of metabolic water produced for unit oxygen uptake. When burning fat, to produce 100 gm. of metabolic water, 255 gm. of oxygen must be absorbed; to produce 100 gm. of metabolic water from carbohydrate only 213 gm. of oxygen need be used. I believe therefore that an animal living on fat may actually be worse off as regards the production of metabolic water than one living on carbohydrate.

The same conclusion may be arrived at in a different way. Fat has a much higher calorific value than carbohydrate, but while for every 1,000 calories produced by burning fat only 120 gm. of water are produced as a by-product, when carbohydrate is burnt 130 gm. of water are manufactured for the same calorific yield. Thus if an animal performs the same sort of activities on a predominantly fatty diet, it will actually produce less water than on a predominantly carbohydrate diet.

There is one way in which the conclusion given above may need to be modified. Possibly when an animal is metabolizing fat it may obtain the extra oxygen, not entirely by increased ventilation, but partly by an increased utilization of the oxygen in the blood, with a consequent reduction of the venous blood to a level lower than that found when carbohydrate is burned. We do not know that this actually happens, for there appears to be little information concerning the composition of venous blood when different food substances are used. If it does, however, carbon dioxide production in relation to the control of ventilation must be considered. 244 gm. of carbon dioxide are produced for each 100 gm. of metabolic water manufactured from fat, and 293 gm. of carbon dioxide for 100 gm. of water from carbohydrate, so ventilation (largely controlled by carbon dioxide) and therefore evaporation from the lungs may actually sometimes be greater when carbohydrate is being used. This does not invalidate the conclusions given above concerning the amounts of water produced for each calorie when different foodstuffs are burned, and without further work it is very doubtful whether such differences in the oxygen content of the venous blood of normal resting individuals are to be found. In general then, it is clear that fat cannot in a given time give appreciably more metabolic water than carbohydrate, and most of the evidence suggests that it gives considerably less.

The only advantage of fat over carbohydrate under conditions where desiccation is likely (in deserts or lifeboats at sea) is that a smaller weight will have a higher calorific value and will give more water of metabolism than the same weight of carbohydrate. However, carbohydrate foods are generally less bulky, more easily stored and non-perishable; furthermore, very fatty diets are likely to give nausea and acidosis.

Desert animals store fat in their bodies because fat is the only food substance which animals can store in any quantities. But they store the fat as a food and not as a water reserve, for in deserts starvation is as great a danger as desiccation. In fact, many animals avoid desiccation by living in burrows where an almost saturated micro-climate is found even although the outside air may be extremely dry.

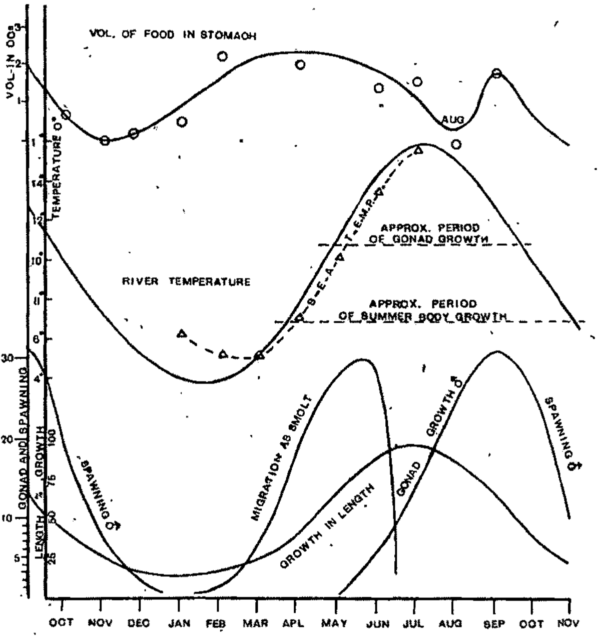
Biology of Young Salmon (*S. salar*, Linn.)

IN the period immediately preceding the outbreak of the present War a close study had been made of the biology of young salmon, that is, salmon parr (*S. salar*), in various localities of Great Britain and Ireland[1-3]. It seems advisable in the existing conditions of war to review these investigations and particularly those carried out on the Welsh Dee. The accompanying figure correlates in one picture much of the work done on this river; the results obtained in other localities are not very different.

It would appear from all these investigations that rapid growth is related to feeding only at or above a particular temperature-level and may, moreover, be checked in the male by the later stages of gonad growth and spawning. Gonad development in the male is correlated with an accumulation of fat reserves following rich feeding and apparently also with a particular temperature-level. Spawning in the male is correlated with a rapid fall in temperature and a falling off in the amount of food taken (and available). Fat reserves are used up in the young male in the production of gonad but not in the female. An increase in the amount of food taken is not followed *at once* by an accumulation of mesenterial fat reserves, nor apparently an improvement in 'condition', ($K = W/L^3$), but the laying down of mesenterial fat is soon followed by testis development in the males. Smolt migration begins during the early phase of acceleration of growth in body-length, and appears to receive an early impulse about the time of the rise in river temperature from the minimum. A close relation exists between river and sea temperature at the time of migration. There is no information available yet on metabolic state at the time of migration, but mean size is known to vary with the type of environment.

How far the correlations brought out in these investigations apply to all habitats of young salmon remains to be found. The results from the Rivers Dee (Wales), Eden and the Eire rivers do not appear to be strikingly different, nor are the environments very dissimilar from a broad view, and it is recognized that strongly contrasting environments are needed to evaluate the correlations noted above. Investigations similar to and indeed more extensive than those carried out on the Dee are required from markedly different environments. Ideally, the environments chosen should cover the geographical range of the species, so that the extreme habitats in Great Britain, for example, northern Scotland and southern England, may not be sufficiently critical. The inclusion of habitats in Scandinavia and France in the investigations would greatly enhance the value of a survey on the biology of young salmon.



SOME FACTORS IN THE BIOLOGY OF SALMON PARR.

Vol. of food (Carpenter[6]) is given in c.c.'s as a criterion of food value; nutritive value estimations would be better; *River temperature* is given for the Dee (Wales) as monthly means over a period of ten years (Jones and Orton[3]); *Sea temperature* for the Liverpool Bar L.V. (1928–32) given by the broken line approximates to (and is normally lower than) that of the Dee Estuary during the migration period (Orton[8]); *Gonad growth* in the male is derived from the numerical stage of gonad × percentage of those stages in the total sample examined (Jones and Orton[3]); *Spawning* is represented simply as the decline of the graph for gonad growth in the male population; *Growth in length* is an arbitrary curve from Jones's unpublished work; *Migration as smolt*, including appearance of smolt coat, is an arbitrary curve mainly from summarized observations of J. G. D. Watts and G. M. King, during a period of 13 years, in Annual Reports, Dee Fishery Board, 1929–41; *Condition and mesenterial food reserve* follows closely the graph for gonad growth in the male (Orton and Jones unpublished, Allen[2b], Frost and Went[5]).

When data relating to a wide range of habitats are available it may not be difficult to deduce the common metabolic states and physical conditions (if any) that (1) precede and accompany and govern size at migration, govern (2) growth, (3) fat deposition, (4) gonad development and (5) spawning of the males.

The problems in the biology of young salmon therefore demand team work not only in each of several localities but also on a broad geographical basis Simultaneous team work in localities in Great Britain was being attempted at the outbreak of war; it may well be desirable in the solution of the problems to extend the team work to other countries for the purpose of comparing an adequate range of environments when investigations of this kind can be resumed.

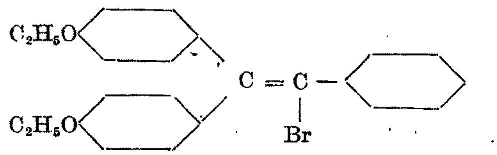
A New Synthetic Œstrogen with Prolonged Action when Given Orally

THE discovery of the synthetic œstrogens put at our disposal substances which had the great advantage of being highly active when given by mouth. Of these, stilbœstrol has been extensively used and has proved of great value. This substance, however, has only a short period of action so that clinically it has to be given at frequent intervals in order to produce a sustained effect.

We have examined a large number of substances, including derivatives of triphenyl ethylene, in an attempt to obtain an œstrogen which would produce a prolonged effect not only when given by injection, but also when administered orally, and have obtained one substance, αα-di-(*p*-ethoxyphenyl) β-phenyl bromoethylene (D.B.E.), which appears to be promising from that point of view. The formula of D.B.E. is as follows:



The activity of the substances was determined on groups of ovariectomized mice by quantitative methods previously described [1,2].

TABLE 1. COMPARING THE DURATION OF ACTION OF VARIOUS ŒSTROGENS ADMINISTERED SUBCUTANEOUSLY IN OVARIECTOMIZED MICE

Substance	Dose (μ gm.)	Duration until action halved (days)
Stilbœstrol	0·1	3
	50	9
	500	16
Œstradiol dipropionate	100	21
	500	50
Triphenyl chloroethylene	50	0
	100	12
D.B.E.	20	4
	100	93

The œstrogenic actions of D.B.E. and of a number of other œstrogens are compared in Table 1. These effects were obtained when these substances, in solution in oil, were injected subcutaneously into groups of mice in four doses over forty-eight hours.

TABLE 2. COMPARING THE DURATION OF ACTION OF VARIOUS ŒSTROGENS ADMINISTERED ORALLY IN OVARIECTOMIZED MICE

Substance	Dose (μ gm.)	Duration until action halved (days)
Œstradiol	5	3
	50	7
	500	17
Stilbœstrol	0·1	3
	500	20
Triphenyl chloroethylene	100	4
	500	13
D.B.E.	10	7
	50	21
	500	38

It will be seen, that though D.B.E. has a relatively high threshold, a small increase in the dose produces a very marked prolongation in the duration of its action. In this respect it is similar to the di-esters of œstradiol.

For the oral administration, the substances, in solution in oil, were introduced into the stomach by means of a stomach tube; a single dose was given to each mouse. Each test was carried out on a group of ovariectomized mice. The activity of D.B.E. and of a number of other œstrogens so administered is given in Table 2.

It will be seen that D.B.E. has an oral threshold similar to that of œstradiol and much higher than that of stilbœstrol. Unlike œstradiol and stilbœstrol, however, a relatively small increase in the oral dose of D.B.E. produces an appreciable increase in the duration of its action. It would therefore seem that, after absorption from the alimentary canal, D.B.E. is stored somewhere in the body and slowly released to produce a prolonged effect.

It is intended to investigate the question of the storage of D.B.E. and its possible clinical value.

The expenses of the biological part of this investigation have been defrayed by a grant from the Medical Research Council.

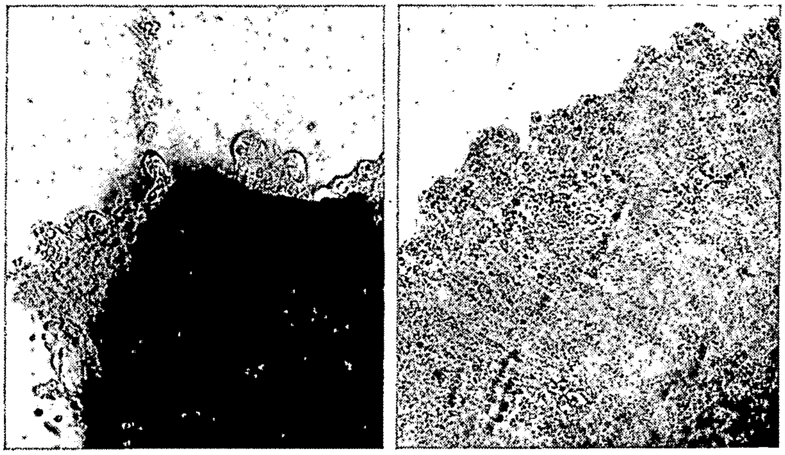
Effect of Extracts of Heterologous Adult Tissue on Cell Growth *in vitro* and their Use in Wound Healing

IN previous papers[1] we have reported that the ability to promote the growth of cell cultures *in vitro* is common to extracts of various tissues and organs of adult animals, and that this property is independent of the rate of proliferation of the tissue from which the extract is made. Extracts of some mitotically stable organs of adult fowl (brain, cardiac muscle, smooth muscles) activate the growth-rate of chicken fibroblasts to a remarkably high degree.

Further investigations were carried out to determine whether the growth-promoting ability of adult tissue extract is restricted to homologous cells only or manifested also on cells from foreign species. Carrel[2], who was aware of the growth-promoting power of homologous adult tissue extracts, stated that whereas embryo extracts, homologous and heterologous, are equally effective, extracts of heterologous adult tissue stimulate cell-growth only slightly if at all.

The growth-promoting activity of tissue extracts was tested in the present experiments on stock cultures of chick heart fibroblast according to the technique previously described[1]. The extracts tested were prepared from heart muscle of sheep, cow, rabbit and dog. The growth of the cultures in media containing these extracts was compared with the growth of control cultures in a medium containing chicken heart muscle extract. Consistently uniform results were obtained. Heart muscle extracts of all species used have the power of strongly stimulating the growth of chicken cells *in vitro*. The pattern of the cultures and the appearance of the individual fibroblasts vary somewhat with different extracts, but the growth-stimulating effect of heterologous tissue extracts was in every case of the same order of magnitude as that of homologous extract.



a *b*

FIVE-DAY-OLD CULTURES OF HUMAN SKIN EPITHELIUM. LIVING (× 40)
(*a*) in protective medium; (*b*) activated with extract of heart of adult fowl.

These experiments were further extended to include human tissue. The question was examined whether and to what extent the growth of human epithelium *in vitro* is stimulated by extracts of heart muscle from adult fowl. Skin fragments fresh from operation (fragments of skin were obtained through the kindness of Major M. C. Oldfield) were explanted in Carrel flasks and maintained both in protective medium and in medium containing 15 per cent chick heart extract respectively. Skin fragments maintained in the protective medium (fowl plasma and Tyrode solution) showed only a few epithelium buds and shoots after five days of incubation. Fragments grown in medium containing heart extract, on the other hand, were after five days surrounded by a broad zone of densely packed epithelial cells. The growth area of newly formed epithelium in human skin cultures activated by adult tissue extract bore a ratio of 16 : 1 to that of non-activated cultures (average of fourteen experiments). The growth-accelerating effect of extract of adult fowl heart on human epithelium is thus very pronounced.

In view of the experiments reported above, the following consideration seems justified. Attempts have been made by various workers[3] to assist the process of wound healing by means of cell growth-promoting tissue extracts. The results of these experiments have been consistently favourable. The process of wound healing is accelerated, and non-healing wounds can be induced to heal under the influence of extracts which activate cell growth. Despite the favourable results of the clinical experiments, the use of growth-promoting tissue extracts in wound treatment did not find general application. In all clinical trials carried out, the source of growth-promoting substances was embryo extract, which is not particularly easy to obtain and quickly loses its growth-promoting power. This circumstance rendered this method completely impracticable. The fact that extracts of heterologous adult tissue are capable of strongly stimulating the proliferation of human cells suggests a new and simple solution of the problem. Extracts of adult tissues combine a twofold advantage : they are highly potent and they are easily available.

To sum up. Extracts of heterologous adult tissues stimulate cell growth *in vitro* to a high degree. Their efficacy in wound healing is to be expected, but has to be proved by therapeutic experiments. Treatment of wounds by adult tissue extracts is being carried out in the Surgical Department of the Hadassah-University Hospital, Jerusalem. A paper reporting the results of clinical trials is to be published shortly.

This work has been aided by a grant from the Dazian Foundation for Medical Research.

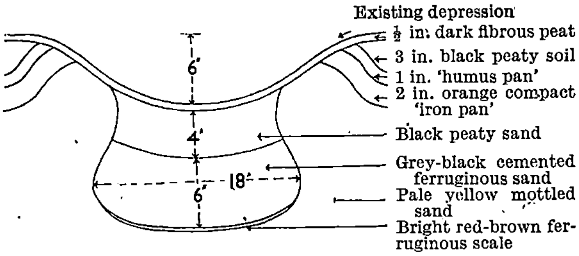
Human Activities and Soil Characteristics

There are probably few lowland areas in Great Britain where the development and characteristics of soils have not been materially altered by the impact of human activities ; it is, nevertheless, often assumed that portions of the New Forest have been little influenced by man's interference. Investigation would suggest, however, that such is far from being the case, and that comparatively unobtrusive factors have exerted effects which often obscure and complicate the fundamental soil-forming processes.

Recently, as part of an effort to improve the quality of the forest grazings, a fairly level 'moor' at Pilley near Lymington was ploughed ; the existing flora consisted mainly of *Erica tetralix* and *Calluna vulgaris* (dom.), with *Molinia cœrulea, Agrostis setacea, Ulex minor*, Carex and Lichen, in an open community. Over a considerable area, the occurrence was observed of parallel orange-coloured bands, extending in varying directions on the bottoms of the furrows, at about 4 in. below the surface. In a few instances these bands could be identified with the impressions of old cart tracks ; a typical soil profile is shown in the diagram.



According to local informants, marl was at one time carried across the moor from pits to farms lying beyond its margins. The marl carting apparently commenced about 1840, using, in the early days, oxen teams with broad-wheeled carts ; the practice was finally discontinued around 1890.

It would appear possible that the pressure of the wheels broke the continuity of the iron pan, which was forced downwards, below the rut, while the adjacent pan outside the rut was forced up and exposed at the surface. The depression was afterwards filled by washing in from the sides, and in many cases has practically disappeared. The exposed ferruginous material underwent a change in colour from orange to dull brown, and the whole became covered by a thin horizon of humous material, of recent origin.

Taken as a whole, the soil characteristics of this moor are now rather variable. Apart from the profile already described, at certain sites a typical podsolic bleached A^2 horizon is discernible ; at others, a few yards distant, the iron pan is overlain by a black peaty sand. The 2-in.-thick iron pan appears nowhere to lie more than 6–8 in. below the surface, while the superficial A° horizon of peat is only about ½ in. and the bleached sandy A^2 about 2 in. in depth.

It is difficult to believe that the present poorly developed eluvial horizons correspond with the strongly developed illuvial horizons now observable, and it is suggested that the original A° and A' horizons may have been removed by the intermittent operations of peat cutting and heath burning, known to have been practised in the past.

In the opinion of the writer, the foregoing serves to illustrate the difficulty in interpreting the various factors which have affected soil-forming processes, even in an area which, at first sight, might be thought to have developed under the influence of purely natural agencies.

A New Synthesis of X-Ray Data for Crystal Analysis

IT is unfortunate that Dr. Yü is not more easily accessible to direct correspondence about his new synthesis of X-ray data for the determination of crystal structures[1]. If the method is what he claims it to be, it is certainly an important advance; the details he gives, however, are not self-explanatory, and physical reasoning would suggest that the advantages he claims cannot possibly be obtained from the X-ray data given by any actual crystal.

The number of X-ray spectra obtainable from a crystal is limited by the natural decrease in intensity with angle; thus there is a limit to the resolving power of the 'X-ray microscope'. This limit is not, as for optical instruments, an artificial one that depends on the conditions of experiment; it is an expression of the fact that atoms have a natural diffuseness due to their finite size and thermal motion. Crystals composed of dimensionless atoms would give spectra that did not, on the average, decrease with angle.

Now Yü has claimed, in effect, that he has produced a synthesis with no limit to the resolving power. To do this he produces a set of quantities E_h which are related to the observed intensities but which are so corrected that they do not, on the average, decrease with angle. This, in agreement with my statement above, is the condition necessary for infinite resolving power. These E_h's are then multiplied by the quantities $a_{\mu h}$; Yü does not define these but states that they decrease with h so that his series $\sum\limits_{h=0}^{\infty} a_{\mu h} E_h$ can be terminated at a reasonable value of h. It seems to me, however, that if the high-order intensities are not included in the series, the resolving power cannot be infinite; that the convergence is in the a's and not in the E's is immaterial.

The method, of course, cannot be completely understood until all the details are available. Nevertheless, I suspect that there is no essential difference between Yü's synthesis and Patterson's, except that Yü considers his as a function that has appreciable values only at discrete points, whereas Patterson's is continuous. It is doubtful whether this concept has any advantages over the older one, but it will be interesting to see whether the publication of Yü's $a_{\mu h}$'s will lead to any simplification of the processes involved in the summations.

A Relativity Query

As is well known, Einstein's theory of gravitation predicts three small effects not previously known. Two of these are the deflexion of light rays passing near the sun and the advance of Mercury's perihelion. I have found that these are given very simply by Fermat's principle and the principle of least action respectively.

The matter can be put shortly, as follows:

$$\delta \int \sqrt{1 + \left(r\frac{d\theta}{dr}\right)^2}\, dr = 0, \qquad (1)$$

an application of Fermat's principle, gives the straight line; r and θ are two-dimensional polar co-ordinates.

$$\delta \int \sqrt{\frac{2\,km}{r} - C}\,\sqrt{1 + \left(r\frac{d\theta}{dr}\right)^2}\, dr = 0, \qquad (2)$$

an application of least action, gives the ellipse. Now repeat the two equations but suppose that the medium is very slightly ælotropic, writing

$$\sqrt{n_r^2 + \left(n_\theta\, r\frac{d\theta}{dr}\right)^2}\, dr$$

for the element of optical length where

$$n_r = n_\theta^2 = \left(1 - \frac{2km}{rc^2}\right)^{-1}$$

and c is the velocity of light. The application of Fermat's principle then becomes

$$\delta \int \sqrt{n_r^2 + \left(n_\theta\, r\frac{d\theta}{dr}\right)^2}\, dr = 0; \qquad (3)$$

and the application of least action

$$\delta \int \sqrt{\frac{2km}{r} - C}\,\sqrt{n_r^2 + \left(n_\theta\, r\frac{d\theta}{dr}\right)^2}\, dr = 0 \qquad (4)$$

The two equations give respectively *exactly* the same paths as Einstein obtains for the passage of the light ray and the planet in the sun's gravitational field. The results come out very easily. It is the slight ælotropy of the medium that constitutes the difference between Newton and Einstein. The first three equations can be obtained from the final one by omitting the appropriate terms.

Now these seem to be important results, and there is a strong probability that they have appeared in print before; but I have not been able myself to find a reference to this having happened, neither have authorities whom I have consulted. Can any reader of NATURE give me information?

Geologists in War-Time

MIGHT I suggest that the lack of interest shown in the work of geologists in war-time, complained of by Dr. F. Coles Phillips in NATURE of April 4 last, is a continuation of a similar lack of interest in peace-time? This subject was dealt with ably by Prof. P. G. H. Boswell in his presidential address to the Geological Society of London last year, and it is now being realized that, admirable and fundamental as pure science may be, any branch of science which is not linked to everyday life is bound to suffer the fate that is being suffered to-day by pure geology. Mining and oil geology have already robbed the science of many potential adherents, but what has struck me most since my interest in geology was aroused over twenty years ago has been its complete neglect of its possible application to allied sciences. Thus to take only those cases of which I have personal knowledge, building stones, road and building aggregates, and greater than these, soil mechanics, are all examples of subjects which could have been developed by geologists, but which have been left by them to chemists, physicists and engineers with markedly beneficial results to those branches of science and a corresponding loss to geology.

It should be realized by geologists that the natural corollary to the statement made above is that a greater interest in allied sciences by them is needed; the impetus must come from them; it will certainly not come to them from other quarters.

RESEARCH ITEMS

Development of the Liver in the Salmon

Helen I. Battle has investigated the hepatogenesis of the Atlantic salmon (*Salmo salar* L.) (*Canadian J. Res.*, 20, Sec. D, No. 4; April, 1942). Little is known about the early embryology of the liver in teleostean fishes, expecially of the Atlantic salmon, and this detailed study is a valuable contribution to the subject. Many problems of interest arise, not merely in the embryonic phases but also following the larval period, when the liver undergoes an enlargement, and a differential growth accompanies the metamorphosis of other structures already observed as constituting the transition from parr to smolt. The present work deals with the gross morphological changes in the liver during development from the initial appearance of the 'anlage' in the 4-mm. embryo to the adult. A later paper will deal with the simultaneous histogenesis.

American Freshwater Amphipoda

Clarence R. Shoemaker has given useful keys to the families and genera of American freshwater Amphipoda, describes several new species, and redescribes others imperfectly known ("Notes on Some American Freshwater Amphipod Crustaceans and Descriptions of a New Genus and Two New Species", *Smithsonian Misc. Coll.*, 101, No. 9. Smithsonian Institution of Washington, Publication 3675; 1942). Among the new species are some interesting cave-dwellers. One is from a cave in Cuba described first by Ada L. Weckel and now placed in the new genus Weckelia, another is a large Crangonyx from caves in Pennsylvania, discovered by Kenneth Dearolf, representing a new species, *Crangonyx dearolfi*. Four families of freshwater Amphipoda are so far known from America: Corophiidæ, Talitridæ, Haustoriipæ and Gammaridæ. Only one genus each is represented in the Corophiidæ (Corophium), Talitridæ (Hyalella), and Haustoriidæ (Pontoporeia), but there are two sections in the Gammaridæ, the Gammarus and Crangonyx sections, with several genera.

Translocations in *Appotettix eurycephalus*

R. K. Nabours, F. M. Stebbins and W. R. B. Robertson (*J. Exp. Zool.*, 38, 239; 1941) report further results from X-raying males of *Apotettix eurycephalus*. Among the translocations observed in the progeny were two translocations: between chromosomes 1 and 4 and between chromosome 1 and the *X*-chromosome. Genetical analysis of the genes *OTG* and *W* and cytological evidence enable the authors to place the genes on chromosome 1 in respect to the centromere. In the case of the reciprocal translocation involving the *X*-chromosome and chromosome 1, it was found that the autosomal gene *W* had become transferred to the *X*-chromosome and showed sex linkage. Considerable data of the viability of animals with different chromosome abnormalities were obtained and it was shown that quite frequently a zygote with an abnormal chromosome constitution lived until the third or fourth instar.

Localized Chiasmata in *Fritillaria Meleagris*

Meiosis in normal *Fritillaria Meleagris* is characterized by the bivalents being held together at metaphase by chiasmata strongly localized near the centromere. By treating the early stage of meiosis with colchicine and with heat, H. N. Barber (*J. Genetics*, 43, 359; 1942) has been able to analyse the phenomenon more fully. He finds that heat treatment at the time of chromosome pairing reduces the chiasma frequency and tends to increase the proximal localization. On the other hand, treatment with colchicine reduces the chiasma frequency, and localization disappears. Indeed with colchicine pairing takes place at several places on the chromosome, which results in considerable interlocking. The interpretation given is that heat reduces the time limit of pairing and thus reduces the chiasma frequency without influencing the general method of pairing. Colchicine, on the other hand, by influencing the region of the centromere, reduces its advantage in pairing and slows the general rate of pairing. Normal localization in *F. Meleagris*, therefore, is taken as depending on an early limit of pairing and a centromere control of the contact points of the chromosome.

Respiratory Channels in the Tomato Fruit

K. A. Glendenning, biochemist at the National Research Laboratories, Ottawa, has followed up some observations upon the respiratory activity of the detached fruit of the tomato with a study of the behaviour of the fruit while still attached to the plant (*Canadian J. Res.*, 20 (4); April, 1942). There is clear evidence that the ripening colour change on the vine involved at first a rise in respiration, to the yellow orange stage, followed by a decline as the fruits ripened to full red. A similar respiratory drift had been noted in detached fruits, and there the remarkable fact had been observed that this rise and fall may be abolished completely and the associated colour changes seriously modified, by blocking the stem scar area with melted wax. It is known that the act of detachment does not interfere seriously with respiratory activity so it was interesting to see if any region could be blocked in the still attached fruits so as to modify the respiratory ripening changes similarly. It was found that fruits failed to show the normal colour changes when melted wax was applied to the area of the fruit ordinarily covered by the calyx and also to the parts of the pedicel immediately adjacent to the receptacle and to the receptacle itself in the angle between pedicel and fruit. Most of these fruits abscissed relatively early. The area of free gaseous interchange in the attached tomato fruit thus appears to be associated with this surface region of the fruit.

Carboniferous Lycopods

J. M. Schopf's recent work on American material makes valuable progress with the fossil Lycopods. One paper (Illinois Geol. Surv., Rep. of Investigations, 50) deals with isolated megaspores, which are now coming to be used as one of the means for recognizing individual coal seams. Various types are discussed, including ones belonging to Lycopod seeds for which a genus is made. A second paper (*ibid.*, Circular 73) consists of a critical discussion of the Lycopod seeds Lepidocarpon, which are numerous in America. A third (*ibid.*, Report of Investigations, 75) deals with the rather obscure genus Mazocarpon Benson. A new species is described from abundant male and female cones which are so well preserved that the single large archegonium of the female prothallus is clearly seen. Various points are cleared up; for example, the ligule which is recognized; and it is interesting that the idea that this is the cone of Sigillaria is strongly supported, and also that the megaspores are shown to be one of the commonest types in coal seams. The idea that this cone shows an approach to the seed production of Lepidocarpon must be given up. It is specialized on different lines, but at the same time it is not yet clear how the spores were shed. This remarkable material should be able to provide information on this and other points of the life-history of Sigillaria.

Constitution of Agar

IN some experiments described by W. G. M. Jones and S. Peat (*J. Chem. Soc.*, 225 ; 1942) evidence is presented that agar is the sulphuric acid ester of a linear polygalactose, the unit chain being composed of nine *d*-galactose residues mutually combined by 1 : 3-glycosidic linkages, and terminating at the reducing end by a residue of *l*-galactose, united with the rest of the chain by a glycosidic linkage engaging C_4 and not C_3. The *l*-galactose member is esterified at C_6 with sulphuric acid. This structure is shown to account for some reactions studied. The interesting suggestion is made that in the biological synthesis of agar a sulphate fulfils a similar function to the phosphate in the enzymatic synthesis of starch from glucose 1-phosphate, and this is explained more fully. The phosphoric acid is not retained in the starch, but with the agar the sulphuric acid, functioning as *d*-galactose 1-sulphate, remains with an adjusted orientation as an integral part of the molecule.

Copper Compounds

THE hydrated blue gel thrown down by addition of a base to a cupric salt solution passes into black cupric oxide at a rate depending on the conditions of formation. H. B. Weiser, W. O. Milligan and E. L. Cook (*J. Amer. Chem. Soc.*, 64, 503 ; 1942), by phase rule and X-ray diffraction methods, have shown that $Cu(OH)_2$ is the only compound formed in the $CuO—H_2O$ system, although four definite lower hydrates have been reported by another worker. The brown to black oxide CuO is formed by spontaneous decomposition of the cupric hydroxide gel, this being (as has long been known) accelerated by contact with dilute alkali. If the ratio of equivalents of cupric sulphate to alkali in a mixture is less than or equal to 1, the blue precipitate is pure cupric hydroxide ; if it is equal to or greater than 1·33, the precipitate is basic sulphate, $4CuO, SO_3, 3H_2O$, identical with the mineral brochantite ; if the ratio is 1·25, it is a new compound, $5CuO, SO_3, xH_2O$; if between 1 and 1·25 a mixture of this and cupric hydroxide ; if between 1·25 and 1·33 a mixture of the two basic sulphates formulated above. The identity of the new basic salt $5CuO, SO_3, xH_2O$ was established by several methods, including analysis of crystals.

Renin

IT was known that the intravenous injection of saline extracts from fresh kidneys causes a prolonged rise in blood pressure, and this has been shown to be due to the presence in the extract of a protein renin, soluble in water and dilute salt solutions, insoluble in alcohol and deactivated by heat and capable of purification by fractional precipitation by ammonium sulphate. O. Schales (*J. Amer. Chem. Soc.*, 64, 561 ; 1942) has now described a method by means of which it can be obtained in good yields and with a high degree of purity. This is a long and rather complicated process, which is set out in detail. Renin appears to be a pseudoglobulin. No evidence of the presence of a removable prosthetic group has so far been found.

Structure of Complex Fluorides

INTEREST has recently been taken in the determination of the structures of complex ions containing fluorine and apparently having the unusual co-ordination number of 7. Cubic crystals of potassium and ammonium heptafluozirconates contain the ZrF_7''' ion with point-group symmetry of $C_{3y} - 3m$. The fluoxyniobate ion $NbOF_6'''$ has a similar configuration in cubic crystals of $K_3 NbOF_6$. Monoclinic crystals of the isomorphous K_2NbF_7 and K_2TaF_7 contain the complexes NbF_7'' and TaF_7'' with the point-group symmetry $C_{2y} - mm$. J. L. Hoard and M. B. Williams (*J. Amer. Chem. Soc.*, 64, 633 ; 1942) have now examined the structure of $(NH_4)_3SiF_7$ by X-ray analysis. The result shows that this does not contain an ion with 7-covalency similar to those just mentioned, but the crystals are ordered aggregates of $NH_4^{\cdot}$, F' and octahedral SiF_6'' ions, and hence the salt (which was discovered by Marignac in 1859) can best be represented by the double-salt formula $(NH_4)_2SiF_6, NH_4F$. Some of the interatomic distances are 10 per cent larger than anticipated for the co-ordination number involved. This is correlated with the very soft character and limited stability of the crystals, and the unusually large effects of thermal vibrations on the observed intensities of the diffraction maxima.

Defects in Glassware

AT a meeting of the Society of Glass Technology on June 16–17, A. J. Holland, Eric Preston and W. E. S. Turner presented a paper on "Cords, Surface Finish and the Quality of Glassware". Omitting from consideration those defects classed as stones, seeds or blisters, the two main defects which impair the quality of glassware are those which occur in the body of the glass due to the presence of 'cords', and those present on the surface and which are largely dependent on mould conditions. A comparison was made of direct-shadow, polariscopic and photo-optical methods of determining cordiness. For routine comparisons and control, the direct-shadow method is extremely sensitive and excellent degrees of cord estimation can be accomplished in this way if preliminary standards are first set up over a sufficiently wide range—a 'figure of merit' was obtained depending on the range of cordiness covered by the reference samples. A thermostatically controlled centrifuge was also set up to separate from finely powdered glass samples glass of differing densities, and in this way an estimate of cord could be obtained either by giving the total density spread of a sample, or the mass-density distribution in the form of a grading curve. The defects which occur on the surface of the ware arising from contact with moulds or tools used in shaping the glass object have been but little investigated. A general comparison of surface conditions can be made, again, by a shadow method, but an optical method is to be preferred. It is even more difficult to give a numerical value for surface condition than for cord, but again a satisfactory 'figure of merit' is obtainable from standards set up and photographed at magnifications between 50 and 100 under conditions of oblique illumination. A scheme is in hand, however, for the utilization of an optical method, which, as in the case of cords, would give a value independent of the observer's judgment. In view of the minuteness of the surface unevennesses, however, it is not anticipated that such a method would be very sensitive.

RECENT ARCHÆOLOGICAL RESEARCH IN TRANSCAUCASIA

PROF. B. A. KUFTIN has been carrying on important excavations in Transcaucasia (1936–39): he made a preliminary report to the Leningrad Institute for the History of Material Culture (*Kratkie Soobshcheniya*, 8, 1–35, figs. 1–18; 1940) and the definite statement of his results has now been produced by the Georgian Academy of Sciences.

In the latter part of the last century, Russian, and some European, museums were flooded with objects from Koban, Samthavro, Kumbulta, Faskau, Rutkha and other sites in the main chain of the Caucasus. They were very handsomely published by the Countess Uvarov and others (for example, *Mat. po Arkheologii Kavkaza*, 8), being obviously of great interest, but being the result of predatory excavations carried out upon very steeply sloping sites had no stratification recorded: things from 1500 B.C. to A.D. 500 were all jumbled up together. Prof. Kuftin excavated a series of sites farther south yielding analogous objects and throwing light on these older finds; for example, things which had been regarded as perhaps decadent and belonging to the last centuries B.C. now turn out to be primitive and can be safely put at 1500 B.C. His sites range from epipalæolithic with the obsidian tools long known in Caucasia, to Hellenistic, Roman and Sassanian times. He has also introduced some order into the different styles of painted pottery, correlating them with those in Elam, Mesopotamia and the regions north of it. He points out that the brilliance of the Van kingdom has concentrated attention on that period within its area, and that we know very little of what went before it.

Without a large number of illustrations it is impossible to convey an intelligible idea of these results. It may be said, however, that Prof. Kuftin has correlated the Cyclopean forts of southern Transcaucasia (*c.* 2000 B.C.) with painted pottery in form and decoration startlingly like Hallstatt forms of a thousand years later.

More surprising are Prof. Kuftin's results obtained on the River Tsalka (lat. 41° 60′, long. 44°), tributary of the Khram, which is being dammed to get electric power. The U.S.S.R. is very good at seeing that such inundations are not made until the area has been examined for archæological remains. First he found barrows with the Hallstatt-like pottery, black glaze over pink; then two other types with light slip, one with shiny black rectilinear ornament, birds, chevrons and swastikas, the other with a cream slip adorned with spirals, volutes and rosettes. The burials were some on the original surface of the ground, others in great pits up to 14 m. long approached by a sloping way. Besides the pots with light slip, these yielded most remarkable metal work; for example, a gold cup adorned with filigree and jewels and set on a pierced base (looking almost like Byzantine work), a silver bucket with hunting scenes in repoussé gold, silver pins with filigree and gems, a silver blade, a necklace with very big beads, an agate pendant set in gold, also grey-blue beads which should help in determining affinities. Another grave had a socketed silver spearhead, not a common thing, and so making one think of the Borodino find, as the gold cups recall Vlči Trn, which likewise seems to belong to a painted pottery culture.

Many of these things resemble those from Ur and Uruk (2500–3000 B.C.) but the technical advance in gold work would seem to point to *c.* 1500 B.C., and the figure-work has some resemblance to Hittite sculpture at Yasilikaya, still untouched by Assyrian influence. There is certainly an element independent of Sumer and not unlike predynastic Egyptian, for example, the Gebel-el-Arak knife-handle. As there are no horses and no iron, we must not bring things down too late. The funeral car found in one tomb is still of the four-wheel type. Whatever the affinities of this new culture turn out to be, it is interesting to set another stone in the arch of painted pottery extending from Baluchistan by Iran and Asia Minor to Transylvania, and if we were bold, we might hope that we have the Hurri or kindred tribes before they moved south.

ELLIS H. MINNS.

PLANKTON OF IRISH LOUGHS*

W. H. Pearsall and Edna M. Lind have made some interesting preliminary researches into the analyses of the ecological relationships of the phytoplankton in numerous small Irish loughs. Twenty-six loughs were studied, ranging from one to seven kilometres in length. These are divided into (1) calcareous loughs (with Chara species abundant), subdivided into those with mainly soil drainage, and those with much peat drainage, and (2) the less calcareous loughs, subdivided into those with oxidized peat drainage, unoxidized peat drainage, the larger stream-fed loughs, and a few left unclassified. This classification agrees well with the algal distribution.

The plankton floras of the different loughs tend to fall into consistently different categories, of which at least four can be distinguished: those of the calcareous loughs with mainly soil drainage, those of the calcareous loughs with much peat drainage, those of less calcareous loughs with oxidized peat drainage, and the large stream-fed loughs. These four represent distinct plankton communities of algæ and as such they could be used in comparison with other plankton communities. The lists as a whole can be analysed to show the habitat range of individual algæ, which should be useful as indicators of water conditions.

The species are classified into three groups: *A*, those mainly characteristic of or most abundant in peaty conditions; *B*, those apparently indifferent to the presence or absence of peaty matter; *C*, those mainly characteristic of, or most abundant in, less peaty conditions. Among the indifferent species occurring in peaty conditions the cosmopolitan dinoflagellate *Ceratium hirundinella* is conspicuous. Diatoms, on the other hand, are less prominent in the peaty loughs but are numerous in the calcareous loughs. It is shown that the bulk of the calcifuge peaty species are distinctive in that they can grow almost equally well in bogs, and the non-pelagic character of these may mean that they are dependent on the presence of an adjacent peaty substratum. The truly planktonic species more characteristic of the less peaty water may have some feature of structure, life-history or metabolism which enables them to maintain a mainly pelagic existence in the large lakes.

The authors regard it as probable that the primary factor in distribution may be the nature of the dissolved solids carried into the lake from its drainage area, a conclusion already reached by the Wests (1909) and by Pearsall (1932). In the peaty loughs where acid conditions predominate these dissolved solids include a large proportion of vegetable organic matter in a slightly oxidized condition with a small amount of decomposition products, in contrast to the less peaty loughs where the organic matter carried into the loughs is comparatively highly oxidized with a large amount of products of oxidation including nitrates. The general effect of such conditions is the greater proportion of diatoms most noticeable in the calcareous loughs.

---

'BOG-BUTTER' FROM SKYE

THE practice of burying kegs of butter or body fat with the object of preserving or improving the flavour of the product continued in Ireland from an uncertain period of antiquity until the end of the eighteenth century. In Scotland, too, similar kegs of fat have been recovered from the peat bogs, though none of as recent date as some of the Irish finds that have come to light. The preservation of fatty substances has always been a problem of human economy which has only been partially solved in our own times with the advent of cold-storage, and the burying of kegs of fat in deep peat holes and leaving them there for any length of time up to seven years, when the flavour is said to be at its best, was probably a considerable contribution towards its solution.

The particular example now described by Prof. J. Ritchie (*Proc. Soc. Antiq. Scotland*, **75**; 1940–41) was discovered by Dr. Hugh Mackay in 1931, while peat was being cut about one mile east of the inn at Kilmaluag at the northern end of Skye. When found, the wooden keg was embedded in the solid peat bank, being tilted a little to one side. It would seem that it had been lowered into a fairly deep peat hole and for some reason forgotten or lost. The body of the barrel was hewn from a solid piece of wood, as also were the circular lid and bottom, though the diameter of the keg was some 15 inches and the tree from which it was made a birch. The workmanship was excellent, the thickness surprisingly uniform throughout. At the top of the barrel where the rim is otherwise bevelled off there are two upward projections nearly three inches high and each pierced by two holes, through one pair of which a cord could be passed for lowering the keg, while a small stick placed through the lower pair would have held the lid in place. Half-way up the body of the keg and not symmetrically placed on its circumference there are two more projections, this time lug-like, the holes having been burnt through the solid wood. It is suggested that these were useful when the keg was slung over a horse's back.

The mass of buttery fat itself has been analysed, but what it was originally could not be certainly determined. Some hairs were present, however, in the amorphous mass, which were mostly those of cattle, though a few human, dog and horse ones were also identified. On the whole, this would tend to suggest that the fat was originally a true butter.

Various methods were used in attempts to date the find—pollen analysis, associated finds, etc.—but no conclusive results could be given. Considering everything the writers are inclined to ascribe the find to the opening years of the Christian era.

M. C. BURKITT.

MELLON INSTITUTE OF INDUSTRIAL RESEARCH

THE twenty-ninth report of the Director of the Mellon Institute of Industrial Research, covering the year ended February 28, 1942, refers to the increase of the industrial research staff from 187 to 205 fellows and from 114 to 150 fellowship assistants engaged on some ninety-five industrial fellowships. Of the eight fellowships terminated during the year, that on carbon blacks as absorbents was concluded by a study of the activation of colloidal carbons with the object of determining their possibilities for use in absorption either in their original form or after treatment. Some carbon blacks prepared in pellet form with a suitable binder and activated by steam showed remarkable increases in their capacities for absorbing vapours and for purifying water.

Special interest is attached to the investigations of the Department for Research in Pure Chemistry, and studies in the chemistry and chemotherapy of modified cinchona alkaloids and related drugs have continued. In experience to date, no beneficial result of quinine cannot be obtained equally well with hydroxyethylapocupreine, a drug which is greatly superior to quinine in pneumonia, in infections of the eye and throat and in certain asthmatic conditions. In view of possible difficulty in obtaining adequate supplies, cinchona alkaloids investigations are in progress aiming at the preparation of simpler compounds which can be prepared from more easily available materials. Studies have also been carried out for the twelfth revision of the U.S. Pharmacopeia, and a number of projects have been subsidized by the Mellon Institute at the Institute of Pathology of the Western Pennsylvania Hospital, particularly on the effects of the sulphonamides on the tissues of the host and on the infecting agent in the tissues. A new sulphhydryl preparation ('Hydrosulphosol') has been found to be of value in the treatment of burns, stimulating rapid healing and discouraging infection. Other work has continued on natural resistance and the common cold, and on the role of certain enzymes in the metabolism of oxygen and carbon dioxide.

Particular reference is made to the work of the Industrial Hygiene Foundation, a combined research and service association for health protection in industry which maintains its headquarters at the Mellon Institute; this Foundation was originally known as the Air Hygiene Foundation, the change of name having been made during the past year. The investigations of the Foundation have covered the effect of arc-welding fumes on susceptibility to tuberculosis, the reactions of living tissues to silica granules, the evaluation of X-ray films for use in physical examinations in industry, and on the present exhaust ventilation systems for control of health hazards. Since early in 1941, the Foundation has been studying sickness absenteeism in industry, and fatigue is also receiving constant consideration. Work on aluminium powder as a possible preventative in silicosis is also reviewed in the report.

Of other industrial fellowships completed during the year reference is made to work on new pre-cast concrete units such as columns, girders and hollow floor and wall panels, the speed of erection of which is the basis of their utility, and an investigation on safety fuses initiated in 1930 has also been completed. With regard to fellowship researches in progress, 'Anthrafloss' is a high-grade mineral wool for insulating purposes developed from anthracite by-products by the multiple fellowship of the Anthracite Industries Incorporated. The multiple fellowship on heat insulation and proofing has assisted in the development of an efficient insulating material suitable for use for temperatures up to and including 800° C. The research programme of the multiple fellowship on plastic metals has resulted in the construction of a large commercial sponge-iron plant. Other fellowships have led to improvement in the manufacture of grey cast iron and steel, while a further fellowship has been devoted to the refining of chromium. Steady progress has been made in the utilization of waste pickle liquor under a multiple fellowship of the American Iron and Steel Institute. Five potential processes for the recovery of materials from this industrial waste have been investigated, including the recovery of free sulphuric acid and ferrous sulphate, the manufacture of iron carbonate and ammonium sulphate, the manufacture of magnesium from low-grade ores by heating with waste pickle liquor and the preparation of sodium sulphate and ferric chloride. Other fellowship researches have related to cast iron enamelling, hollow-ware enamelling materials, flat glass and waste grinding sand from plate glass manufacture. Substantial advances in methods for evaluating the flatness and texture of surfaces has been achieved under the multiple fellowship on plate glass technology.

Under the multiple industrial fellowship on sulphur investigations relating to sulphur cements, reaction of gaseous olefines with sulphur and the use of sulphur as a filtering medium are in progress. The same group has discovered a novel series of accelerators for rubber, as well as prepared further organic derivatives from ammonium thiocyanate. The upgrading of the components of coke-oven light oil, the physical properties of tars and pitches and their improvement, as well as the development of new products from tars, the commercial recovery of cyclopentadiene and the recovery of isobutane and isopentane from natural petroleum and casing-head petroleum have been investigated under other fellowships. The feasibility of installing a butane extraction plant, a product used in the manufacture of butadiene for synthetic rubber, has been demonstrated. Other work in the field of natural gas technology has related to corrosion problems. The multiple fellowship on petroleum has again been very active, its investigations including a study of the chemical constitution of high-melting waxes, research on fractional distillation under diffusion pump vacuum and on the chemistry of petroleum.

The multiple fellowship on organic syntheses established by the Carbide and Carbon Chemical Co. has extended its investigations on the manufacture and application of amines, detergents, lubricants, hydraulic fluids and synthetic resins, and a soluble lubricant for processing woollen fibres has been developed. The fellowship on chemical hygiene has continued its investigations on the physiological effects of new chemical compounds, including the 'Tergetol' penetrants and the acute oral toxicity of glycol derivatives. The multiple fellowship on food varieties has perfected a new type of instant baby cereal, and initiated a project which will survey the whole field of fruit flavours; problems of the rapid tenderization of meat have also been investigated.

Cotton investigations have included studies on the fibre, the practicability and methods of adapting virgin cotton to the manufacture of high-grade papers, and fundamental research on the properties and structure of cotton cellulose and the influence of such processes as mercerization. Encouraging progress has been made in research on cotton-seed, and the industrial fellowship on felt has devised methods for imparting to paper, machine felts and other woollen industrial fabrics markedly improved physical characteristics and resistance to chemical injury, and has also devised a process for rendering wool and woollen fabrics non-shrinking and non-felting. An improved system of wool scouring and scouring control has given an average daily increase in production of more than 75 per cent. A third textile fellowship has led to important advances in processing hosiery yarn, particularly 'Nylon'. Yields and grades of glue have been improved by a fellowship on bone products which has also investigated granular absorbents for use in sugar refining. The fundamental problems of rubber technology are being studied by another fellowship, and 'Raolin', a special chlorinated rubber, developed by a Mellon fellowship research, is being allocated according to Federal Government instructions. Research on polymerizable silicon compounds is being carried on under a further fellowship and certain applications have been proposed which are of potential utility in warfare. Other research is related to the use of plastics in water- and gas-meters and for many other purposes.

HEAT ENERGY FROM RADIOACTIVE SOURCES IN THE EARTH

THE supremely important subject of the amount of heat derived from radioactivity within the earth is the subject of a recent paper by William D. Urry, of the Geophysical Laboratory, Washington ("Heat Energy from Radioactive Sources in the Earth", *J. Wash. Acad. Sci.*, 31, 273–84; July, 1941), who has arrived at some very important conclusions. Older methods of determining the rate of heat production in particular specimens by examining the radon or thoron content were very cumbersome and thus few specimens were examined. Urry has taken a suggestion by the Director of the Laboratory and has examined a method of finding this rate of heat production merely by counting the rate of alpha particle emission in an ionization chamber. He finds that

$$H = 2{\cdot}1 \times 10^{-9} N,$$

where H is the heat produced in calories per gram of specimen per year and N is the total number of alpha particles emitted per gram per hour from the specimen. Heat accompanying the disintegration of potassium must be added to this and is equal to $4{\cdot}3 \times 10^{-6}\, a$ calories per gram per year, where a is gm. K_2O per gm. of specimen. This equation is possible since an error of less than 5 per cent is introduced by taking a fixed thorium uranium ratio in all previously examined types of rocks (acid to ultrabasic) and meteorites (iron and stony) where this ratio ranges from 0 to 20.

The author has examined the question of the variation of this heat production in geological history, and estimates that no significant increase in heat production within the structure of the earth has occurred during the accepted age of the earth (2×10^9 years). Further, in the opinion of Urry, hitherto undetected radio-elements could contribute an appreciable quantity of heat only before $1 \cdot 5 \times 10^9$ years ago.

The new method should facilitate adequate rapid observation (geothermal problems) of great numbers of rock specimens, and should thus in due course present us with a mass of observational data for the study of the influence of heat derived from radioactive materials on the thermal history of the earth, besides contributing data to assist in the solution of present geotectonic problems.

BEHAVIOUR OF SULPHUR IN RUBBER

According to G. G. Winspear (*Bell Lab. Rec.*, 20, No. 8, April, 1942) vulcanized rubber may have a wide variety of characteristics depending on the amount of sulphur, the period and temperature of vulcanization, and the other substances compounded with it. Identical rubber compositions, vulcanized for the same time and at the same temperature, do not always develop the same characteristics. One of the unsatisfactory conditions that sometimes appears is spottiness, indicating a lack of homogeneity in the product. Before the sulphur assumes a position in the rubber molecule, it dissolves, and to secure uniform solution the sulphur is first dispersed evenly throughout the rubber mass. When sulphur and rubber are mixed on a mill the sulphur is dispersed throughout the rubber mass but most of it is in particles of measurable size. Although the particles may be small, and perhaps even invisible to the unaided eye, they are still very large compared to the sulphur molecule, so that the mixture is far from being one where all the sulphur is in immediate contact with the rubber molecules, which is the theoretical state required to give a homogeneous solution of sulphur in rubber. Such an intimate mixture results from a diffusion of the sulphur of each particle following the dispersion on the mill.

If rubber including a small percentage of sulphur is thoroughly mixed and then held for a long enough time at a high enough temperature, all the sulphur will go into solution. From its original particles the sulphur will diffuse until the whole mass of rubber is thoroughly permeated, and if the temperature is high enough all the sulphur will be dissolved. Rubber in thin sheets with completely dissolved sulphur is clear and transparent while if it contains undissolved sulphur crystals it will be cloudy. After a known amount of sulphur has all been dissolved in a sheet of rubber some of the sulphur will begin to crystallize out if the temperature is lowered sufficiently, because the lower the temperature the less sulphur will the rubber dissolve. This precipitation of sulphur will be evidenced by the fact that rubber will take on a cloudy appearance.

The interval between mixing and vulcanization is also important. At the end of the mixing period the rubber is at a fairly high temperature and the amount of sulphur in solution will correspond to this temperature. If the rubber is now set aside it will cool and some of the sulphur will crystallize in fine structure dendritic form. When the rubber is again heated in the vulcanizing process the crystals go back readily into solution. If the rubber is allowed to stand for a more extended period before vulcanization, however, the dendritic crystals gradually change to larger rhombic sulphur crystals, so that when the rubber is vulcanized, the sulphur thus crystallized cannot as readily get back into solution because of the time required for completely dissolving these larger crystals. The formation of these rhombic crystals is undoubtedly the cause of some of the spotty conditions sometimes found in vulcanized rubber.

ELECTRICAL ENGINEERING IN THE UNITED STATES

Archer E. Knowlton, associate editor of the *Electrical World* (United States), in a review (*J. Inst. Elec. Eng.*, 89, Pt. 1, No. 18, June, 1942) of electrical engineering progress in the United States during the past 2–2½ years, points out that in 1941 and after, investigation and research have been redirected substantially towards military measures. Many developments arising out of the pressure for superior arms of every description are already regarded as having great import for the resumption of peace-time pursuits. Weights of electrical equipment are likely to be reduced as the results of iron research, and working temperatures of many kinds of equipment may be increased on account of alloy research.

Outstanding in the latter half of the period under review were the incentives to standardize, to simplify, to eke out and to compensate, in order that suddenly taxed systems could meet the exacting requirements of defence loadings with the least drain on capital, production facilities and installation forces. Also, the technique of proofing overhead lines against lightning made it possible to render a single line practically as reliable in performance as double circuits had been. Higher speed circuit-breakers, reclosure, earth-fault neutralizers, protector tubes, counterpoises, arresters, insulation co-ordination for impulses were all factors in creating effective immunity to the surges which precipitate outages.

In the field of power distribution, reliability of service vied with the imperative need for conservation of capital, and these two somewhat contradictory objectives can claim the bulk of the developments in power distribution. Among these might be mentioned sectionalization of radial feeders, reclosure, networks, banking of secondaries, rebalanced transformer losses, extensive application of corrective capacitors, surveys of thermal margins of apparatus, unit substations, step regulators, improved cables, etc. Change and uncertainty of location of defence loads, as well as the provision of spares for emergencies, have more recently prompted a considerable adoption of portable substations and capacitor banks.

The paper reviews more particularly and in a very condensed form the developments which have taken place in large generators, power generation, transformers, transmission, circuit interruption, relaying, lightning, switching and substations, cables, insulation, capacitors, power distribution, instruments, electronics and electrostatics, motors and control, industrial applications, transportations, rectifiers, electrothermics and electrochemistry, welding, illumination, and certain miscellaneous developments.

ELECTROMAGNETIC WAVES IN METAL TUBES OF RECTANGULAR CROSS-SECTION

AN article by J. Kemp (*Electrical Communication*, 20, No. 2, 1941) shows how the attenuation of electromagnetic waves propagated through the interior of rectangular metal tubes is calculated by the familiar telephone transmission formulæ, the top and bottom of the tube being regarded as zigzag flat-strip transmission lines while the side walls, when suitably disposed, are regarded as transmission lines of another type. From the losses occurring in these lines, the attenuation offered by the tube is obtained in a simple manner. The general formula for the attenuation of all types of waves in metal tubes of all cross-sections has been established by Schelkunoff. Chu and Barrow have also derived attenuation formulæ for all types of waves supported by tubes of rectangular cross-section. The method so far followed has involved the computation of the energy flow in the direction of the tube and the power losses in the walls by means of the Poynting flux theorem.

Electromagnetic waves in metal tubes are characterized by two essential features. There is a minimum frequency below which no waves are supported by the tube. This minimum or cut-off frequency is determined by the shape and the size of the tube. As the wave-length of the cut-off frequency is of the order of the cross-sectional dimension of the tube, the frequencies of the possible waves—for air-filled tubes having dimensions in the centimetre range—are of the order of 10^9 c./s. and above.

The second feature is that there is either an electric or a magnetic intensity in the direction of propagation of the waves, that is, along the tube. For electromagnetic waves in free space the electric and the magnetic intensities are in planes at right angles to the direction of propagation. When, however, waves are restricted to the inside of metal tubes there is, in addition to the electric and magnetic intensities of the free-space waves, either an electric or a magnetic intensity in the direction of propagation. It is customary to use this additional property of these waves for their classification. When there is an electric intensity in the direction of propagation, the wave is designated an E-wave. When there is a magnetic intensity in the direction of propagation, the wave is designated an H-wave.

The article proceeds to the mathematics of the problem and it is shown that the method reveals the existence of a link between two seemingly disjointed branches of telecommunication: (1) telecommunication of the classical character, employing a 'circuit', that is, a system comprising a 'go' and a 'return' path, and (2) telecommunication through hollow metal tubes without a return path in the conventional sense. The final expression for the attenuation constant of waves propagated through hollow metal tubes is derived in a simple manner from the familiar equations for the attenuation of telephone lines, with due regard to the reflexion loss at the junction of dissimilar lines, and the numerical results obtained by the shortened method agree in every respect with those obtained by more elaborate means by other investigators. The simplicity of the method arises from the fact that the telephone transmission formulæ contain implicitly the concepts required in the detailed calculation by orthodox procedure.

FORTHCOMING EVENTS

Wednesday, July 8

INSTITUTE OF PHYSICS (ELECTRONICS GROUP) (at the Royal Institution, 21 Albemarle Street, London, W.1), at 5 p.m.—Discussion on "Cathode Ray Tubes".

Thursday, July 9

INSTITUTE OF SEWAGE PURIFICATION (at Friends House, Euston Road, London, N.W.1), at 2.30 p.m.—Dr. E. M. Crowther: "The Manurial Value of Sewage Sludges"; Mr. J. Hurley: "A Critical Review of Recent Work on Sewage Filtration". July 10 (morning), Visit to Rothamsted Experimental Station, Harpenden, Herts.

Friday, July 10

SOCIETY OF CHEMICAL INDUSTRY (at the Royal Institution, Albemarle Street, London, W.1), at 2.30 p.m.—Annual General Meeting; at 3 p.m.—Presidential Address.

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Discussion on "The Structure and Rotation of Galaxies" (to be opened by Dr. A. Hunter, Dr. H. A. Brück, Sir Arthur Eddington, O.M., F.R.S., Dr. H. Spencer Jones, F.R.S.).

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

HEAD OF THE BUILDING DEPARTMENT of the Croydon Polytechnic—The Education Officer, Education Office, Katherine Street, Croydon (July 9).

LECTURER (WOMAN) IN PHYSIOLOGY, ANATOMY AND HYGIENE at the Dunfermline College of Hygiene and Physical Education—The Executive Officer, National Committee for the Training of Teachers, 140 Princes Street, Edinburgh 2 (July 10).

LECTURER IN PHYSICS—The Principal, Royal Technical College, Salford (July 10).

VETERINARY INVESTIGATION OFFICER—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow (July 10).

TEACHER OF ENGINEERING SUBJECTS at the Redditch Technical School—The Secretary to the Worcestershire Education Committee, Education Office, Church Green West, Redditch (July 11).

GRADUATE ASSISTANT MISTRESS to teach General Science including Biology and Geography—The Principal, Technical Institute, Tunbridge Wells (July 13).

GRADUATE LECTURER IN MECHANICAL ENGINEERING SUBJECTS at the Denbighshire Technical Institute, Wrexham—The Director of Education, Education Offices, Ruthin (July 13).

LECTURER IN PHYSICS (MAN OR WOMAN)—The Registrar, North Gloucestershire Technical College, Cheltenham (July 13).

LECTURER IN COLOURING MATTERS—The Registrar, College of Technology, Manchester 1 (July 13).

VETERINARY BACTERIOLOGIST—The Registrar, King's College, Newcastle-upon-Tyne, 2 (July 20).

WATER ENGINEER AND MANAGER to the Corporation of Swansea—The Town Clerk, The Guildhall, Swansea (July 20).

ASSISTANT FOR WORKSHOP AND GENERAL ENGINEERING SUBJECTS—The Principal, Erith Technical College, Belvedere, Erith, Kent.

ECONOMIC FOUNDATIONS OF A NEW WORLD ORDER

THREE reports of wide importance have appeared almost simultaneously: on "Reconstruction", by the Federation of British Industries; on "Post-war Industrial Reconstruction"; by the Association of British Chambers of Commerce; and on the "General Principles of a Post-war Economy", from the London Chamber of Commerce; with these should also be read a report entitled "Relations with Britain", based on the findings of a committee of editors of the American periodicals *Time, Life* and *Fortune*. The interest which American opinion is taking in post-war reconstruction is reflected in the speeches of her leaders such as Mr. Milo Perkins, of the American Board of Economic Warfare, Mr. Henry Wallace, the Vice-President, Mr. Cordell Hull and Mr. Winant. In Great Britain, Mr. Eden, Mr. Lyttelton, Sir Stafford Cripps and Mr. Herbert Morrison have not lagged behind their American colleagues either in sincerity or in boldness in expression of peace aims.

In broad outlook the three British reports are indeed encouraging. They call for a new outlook. "Quite clearly", says the Federation of British Industries, "we are on the threshold of a new world and the theories and practices of the past cannot be taken for granted in the future. . . . A new situation will have arisen and it will be necessary for industry to suit its methods to that new situation, and not merely to aim at re-creating the pre-war conditions. This does not mean that there should be a complete break with the past, but that changed conditions will, in some respects, need new methods and a positive policy to create them. Such methods will require a fresh outlook, a mutual readiness to face sacrifices, and the determination on the part of all to develop their maximum effort." The actual proposals of the reports, however, betray a spirit quite inconsistent with the courage and faith of their words. There is no hint of the new methods and positive policies, of international co-operation between primary and industrial producers, of a rising standard of life, the equation of consumption with production and not the restriction of production to available consuming power, of a fuller flow of international lending to develop the backward regions of Asia, Africa and America, and of the repayment of world debts in goods. They tend indeed to return to the theories and practice of a restrictive, not of an enterprising past. Anglo-American co-operation seems to be viewed with anxiety.

When set against the American report, the despondency of these reports is remarkable. Of the strength and resources of Britain they give no hint. The spirit and ability that have proved her salvation since the darkest days of 1940 are passed over as if of no account in the post-war world. Britain's greatest asset in her buying power is ignored. The value of research in agriculture is recognized, but as to industry, the Federation of British Industries report alone has a stray reference to the necessity of a most active policy of research to develop new types of exports and to obtain maximum efficiency. Our assets of scientific and technical knowledge and ability are silently discounted. Apart from a wise reminder that it will only be possible to preserve a reasonable standard of life by hard work, and by attaching as much importance to our obligations towards the community as to the rights we claim from it, there is scarcely a reference to the need for great technical efficiency, for more output per head and the development of new techniques and industries.

It is left to the American report to correct this false impression of a decadent Britain brooding over the past, and to assess her true contribution to the technique of economic progress. The assumptions on which the American proposal is based are accepted in theory, if not in practice, by all the British reports: that the United Nations will win a complete victory; that the United States will emerge as the strongest single Power in the post-war world; and that the least America will settle for is a world in which President Roosevelt's four freedoms are reinforced with a fifth—freedom for individual enterprise. With those assumptions goes the belief that there need be no serious post-war depression, and certainly no unemployment; that there need be no major war for a long time to come; that frontiers can be reopened; and that there can be room for both democracy and economic freedom—if the United States choose.

The recommendations are set forth possibly with even more dignity in an article in *Fortune* than by Raymond L. Buell in the report itself. There is frankness and poise, judgment without recrimination, sanity and vision. The first proposal involves the abrogation of the Monroe Doctrine. There have always been some Americans, from John Quincey Adams onwards, who recognized that the Monroe Doctrine was meaningless without the *Pax Britannica* maintained by the British Navy; none the less, a pronouncement of the collapse of isolationism should not pass unacknowledged, for it clears the way to the maintenance of an alliance of the United Nations, particularly with Soviet Russia, China and Britain, to police the post-war world until it is capable of policing itself.

The second proposal goes far beyond the British reports in vision and statesmanship—the proposal that the common security policy should be accompanied by a common economic policy—the creation of a free market area. This second recommendation is that the two countries should unite their economies at once in complete free trade, and allow complete freedom of mutual migration for their respective peoples. The creation of a free market area between Britain and the United States, probably by a joint declaration as a first step, with the creation of joint administrative machinery such as a joint foreign trade council, and accompanied by the elaboration of common demobilization programmes and parallel action to forestall depressions and to promote freer trade, are intended as steps towards a larger area embracing other nations, including the Dominions, which would be invited to join on the same or on special terms. The authors of this proposal are under no illusions as to its dangers or difficulties, but they are rightly viewed in an adventurous spirit and with creative minds not entrenched in the inhibitions of the past.

No real judgment is possible upon the British reports except against the background of the American proposals. Moreover, the latter have their counterpart on the British side in a Political and Economic Planning (P E P) broadsheet on "Anglo-American Economic Policy" which appeared at the end of April, the tentative conclusions of which are strikingly in line with the spirit of the American proposals. Of the three reports, that of the London Chamber of Commerce, though somewhat nebulous, comes nearest to the American proposal.

Starting with the premise that trade barriers are not themselves the disease but merely the symptoms of the disease, and that there is something radically wrong with our economic system, it submits that it is essential, if greater disasters are to be avoided, to change the system so as to ensure that international trade shall tend to raise the standard of living of the backward nations to that of the advanced nations. International trade should be used as a means of mutual aid and advantage to those participating, and competition both within a nation and internationally should be reduced from a life-and-death struggle to healthy emulation. International trade should be an exchange of goods and services of a mutually advantageous character and should not disturb that correct balance between industry and agriculture essential both for social stability and for the health and happiness of the community.

This report shows clearly some of the fundamental problems which must be solved in our attempt to equate effective demand with supply and to eliminate under-consumption: the elimination of the fear and hostility which have been the outcome and the cause of attempts to restrict trade by tariff barriers, subsidies and other measures; the more effective internal distribution of purchasing power; the unwillingness of the primary producing countries, consequent upon their industrialization, to receive imports of manufactured goods previously imported freely; the migration from over-populated to under-populated countries; and the strain which results from the existence of nations with different internal economic systems. There is a healthy note in the Chamber's observations on agriculture, which show that its support should be forthcoming for those measures of re-planning the land which the Ministry of Planning will assuredly be called upon to introduce. For all this, there is little that is positive in the recommendations of the report, which goes no further than to recommend the establishment of appropriate machinery to ensure that slumps may be forestalled through close co-operation between industry and the central bank.

The report of the Association of British Chambers of Commerce, in spite of the warm welcome to clauses 4 and 5 of the Atlantic Charter, with which it starts, is timid in places, but there are unmistakable signs of a new spirit and outlook breaking through its alarms. The Association is prepared, for example, to see the decimal system established as the universal ystem of coinage, and it urges the Government to ake immediate steps for the preparation of widepread schemes of colonial development and an exension of facilities for migration from Great Britain o other parts of the Empire. It presses for early steps to ensure the closest co-operation between the British Empire, the United States, the U.S.S.R. and ll our other allies to provide a more equitable disribution of food and raw materials and a more orderly control of the world movement of manufactured goods. Moreover, if the report is silent as to the need for industrial research and development, it reaffirms the recommendations of its earlier report on agricultural policy in regard to extending the scope of research and making its results more simply available. The importance of agriculture as a major industry is recognized, and adoption of a well-balanced mixed farming policy is recommended, leaving grain crops principally to be imported.

Of the three reports, that from the Federation of British Industries is the clearest in the presentation of the issues, although like the others it falls short of concrete proposals. The first point submitted is that whatever the future form of co-operation in policing the world may be, it is essential that the democracies and other peace-loving nations of the world should take a continuing and permanent interest in ensuring the maintenance of a sufficient force to curb aggression, and that they should be prepared to use that force without hesitation or delay. Otherwise any post-war economic structure will be founded on a quicksand. Reconstruction at the end of the War may be visualized as possessing three aspects. First, the humanitarian phase, that of the immediate relief of stricken countries by the provision and distribution of food, clothing and medical aid to avert famine and pestilence. Secondly, that of economic relief, covering assistance to prevent economic collapse, the restoration and maintenance of essential services, including public finance. The third represents the re-shaping of our own economic life in relation to the needs of other countries, and the elaboration of a system of international trade.

The first two are clearly matters for international collaboration, and, as Viscount Cranborne indicated in his reply for the Government in the House of Lords debate on post-war settlement on June 2, are already receiving the active attention of the Government. The Federation of British Industries in its report submits that co-operation with our allies during the War is the necessary starting-point for eventual wider international collaboration, but that continuing co-operation is also required, inspired by the will and determination to maintain it over a period of years ; it must be sufficiently close yet elastic to enable methods to be suited to unforeseen changes in conditions which may arise from time to time.

A basic principle of reconstruction is that of increasing world purchasing power, and the Federation recognizes that control and restriction of production cannot by itself form a basis for an increase in world prosperity. It submits that serious attention should be given to the development of the Colonial Empires and such areas as China, less from the point of view of the provision of primary products for world use than from that of encouraging developments likely to improve their standard of life. Again, the Federation submits that industry desires the prosperity of agriculture, which is necessary in the national interest, but that the post-war planning of industry, both in regard to home and to overseas trade, will be so vitally affected by the agricultural policy followed in Great Britain that it is essential, if industrial policy is to be on a sound basis, that a decision should be reached, with the least possible delay, as to the future agricultural policy of the country.

Despite an able analysis, the Federation makes no concrete suggestions in regard to the nature of that policy, and similarly its admirable discussion of the many factors involved in national reconstruction, of Government control of industry—the necessity for the continuance of which during the immediate post-war period is admitted—the finance and organization of industry, and of the home market, issue in scarcely one constructive proposal, if we except the attention directed to the important question of the financing of industrial development after the War. This is the more disappointing because the spirit and outlook of whole sections of the report are admirable and balanced, and indicate unmistakably how large is the Government's responsibility for giving a lead and guidance to industry in this matter of reconstruction. The future organization of industry should always be subject to the overriding principle that it must be in the national interest ; finance should be the servant of industry, and not the master—these are unexceptionable principles. But if industry is to take the part in determining its own future organization which the Federation believes it should, industry must not wait upon the Government to take the first step, but by considering all the implications of industrial organization must be prepared with schemes for the more permanent association of Government with industry, which will provide the safeguards required alike in the interests of the nation as a whole and for the stimulation of individual effort and enterprise.

The magnitude of the administrative problems involved in any aspect of reconstruction can scarcely be exaggerated, and the success of whatever measures of reconstruction may be initiated will largely depend on the personnel to whom their administration and execution are ultimately entrusted. In that lies the best hope for the future of the organization now being established for inter-Allied co-operation in the conduct of the War. As the machinery now serving our immediate war purposes brings together the administrators, industrialists and men of science of the United Nations, it prepares the way for the establishment of like machinery for the attack on common problems after the War. It assists the development of a common outlook and demonstrates the possibilities which lie before us when concrete problems are attacked. The new plans which have just been announced to complete the organization for the most effective use of the combined resources of the two countries are an impressive illustration of this.

The Combined Production and Resources Board has been set up under Mr. Donald Nelson and Mr. Lyttelton, and working in close collaboration with the Combined Chiefs of Staff Committee, to ensure the continuous adjustment of production to the ever-changing requirements of the military situation. The Combined Food Board will work in Washington under the direction of Mr. Wickard, the United States Secretary of Agriculture, and Mr. R. H. Brand, chief of the British Food Mission in the United States, proceeding on the principle that the entire food resources of Great Britain and the United States are to be regarded as a common pool about which the fullest information will be exchanged. It needs little imagination to see in such developments a token of the administrative network of international social services which will be required to save Europe from anarchy, famine and disease. Moreover, the treaty between Great Britain and the U.S.S.R. is clear proof that this emphasis upon the combined role of Britain and the United States in war and peace is no derogation of the part that must be played by other great countries. The Combined Food Board, for example, will co-operate with all the United Nations in the use of food resources, as well as collaborate with all the other interested nations in the world in the development, expansion, purchase and use of their foodstuffs.

The importance of making every step fit in with the wishes and interests of other countries is not easily overstressed. For winning the War, or the peace to follow, there must be a basis of all-round trust. The gravest danger is that of petty nationalism on the part of any single country or any single group in any country, and for all the new outlook and spirit in the British reports on reconstruction, they show evidence of a lingering of a nationalist outlook and of a tendency to maintain national claims. The broadsheet on planning issued by PEP is therefore specially welcome as evidence to the contrary of the acceptance in Great Britain and in the United States of international economic collaboration as the condition of a real peace, based on freedom from want.

What is required, according to the planning broadsheet, is the continuous working out, at all levels and on both sides of the Atlantic, of economic principles and methods able to show results in increased and more widespread consumption of goods and services satisfying human needs and in security for occupied populations. A promising approach would be for those interested on both sides of the Atlantic to try to agree on a broad statement of economic purposes, and to develop on this basis a realistic contemporary code of economic behaviour and a calendar of economic crimes. An authoritative international tribunal to deal with disputes as to the 'unfairness' of particular acts, some kind of standing Anglo-American combined economic adjustment board to keep policies aligned and to remove sources of friction, and some sort of general welfare staff, national and international, combining broadly the duties of the new British Production General Staff and those of a social security board are further suggestions.

It is possible to see in recent developments the germ of the organization from which such bodie might evolve. The broadsheet shows, however, wha is even more important—the need for creative thought, for courageous forward-looking minds. As to the hopes, the new outlook and new spirit which have already been aroused, there can be no question If reconstruction is ever to satisfy those hopes, and if there is to be built a new order in which the four freedoms are firmly enshrined, it can only be as men bring to that task determination, vision, courage and magnanimity commensurate with their hopes, and with the effort now being made to gain the victory which must first be won.

NATIVE MEDICAL PRACTICE IN AFRICA

Native African Medicine
With Special Reference to its Practice in the Mano Tribe of Liberia. By Dr. George Way Harley. Pp. xvi+294. (Cambridge Mass.: Harvard University Press; London: Oxford University Press, 1941.) 20*s.* net.

NATIVE African medicine is still an unexplored territory, and it is doubtful if any single individual can arrive at a sound evaluation of native medical practice in any particular area. This would require an entire mission of persons qualified in chemistry, botany, medicine, anthropology and a few other sciences. Nevertheless, a good deal of preliminary investigation has been accomplished by individuals. Thus in South Africa considerable progress has been made in the work of determining the active principles of native drugs and of studying them chemically and experimentally on animals. J. M. Watt and M. G. Breyer-Brandwijk in 1932 published a volume on medicinal and poisonous plants used by the natives of South Africa, with information on 1,713 species which had been investigated in various laboratories. In 1934, D. G. Steyn published a work on the toxicology of plants in South Africa, and in West Africa there is J. M. Dabziel's "The Useful Plants of West Africa", with notes on the medicinal use, by natives, of more than seven hundred species; and so on.

In the present work, Dr. Harley, a medical missionary who has lived for twenty years in the closest contact with the natives of Liberia, and in particular with those of the Mano tribe, makes a valuable contribution to the knowledge of native medicine in its broader aspect. Although he does not appear to include himself in the ranks of 'anthropologists', his work is as much a contribution to anthropology as it is to medicine. This is because native conceptions of disease and native curative practices are intimately bound up with religion and magic; indeed, in order to understand them, it is necessary to have a knowledge of the whole culture of the people concerned. Dr. Harley has this knowledge.

The Mano term for medicine is *nye*, and although there is a tendency to limit this term to rational measures for curing disease, "it is extended in a loose way to include poisons, fetishes, charms and even black magic. Anything with a hidden power under the control of the user is *nye*". To the Mano man he medical and religious or magical elements of *nye* are never completely separated, and if he cannot deduce a cause for a pathological condition from his own everyday experience, he looks for it in the supernatural.

Among Mano remedies which we would describe as rational are ointments, poultices, mud baths, sweat baths, eye-lotions, fumes for headaches, splints for fractures, incisions over abscesses, and the use of counter-irritants. The treatment for poisoning consists largely of emetics and cathartics, as well as the use of precipitants such as tannic acid and rubber latex. (Dr. Harley has very little to say about antidotes.) Surgery is limited to bone-setting, blood-letting by small, shallow incisions, circumcision and scarification of tribal marks—the last two being performed in the secrecy of the Poro and Sande Societies. There is also a practice closely parallel to our custom of performing an autopsy on cases in which the cause of death is obscure. The native leech will open up a cadaver and remove a diseased organ, especially if this organ had been the seat of a tumour which was recognizable before death and supposed to be witch-substance. The diseased organ will be removed and buried separately, so that the spirit of the deceased will not transmit the disease to some other member of the family.

Cases of smallpox are isolated, but inoculation is not practised by the Mano, though it is by numerous other tribes in West Africa. In some areas of Africa inoculations are also given against snake bite. In speaking of the widespread custom of drinking the ink used in writing verses of the Koran, Dr. Harley says that "the possible value of this ink must be attributed to the herbs from which it is made". But the practice is surely pure magic and nothing else. Again, in speaking of the practice of giving sun baths to babies, Dr. Harley observes that "whether this sunning is responsible or not, there were only three recognizable cases of rickets in a series of 8,291 admissions to the Ganta dispensary". But the cause of rickets is well established and sunning can scarcely be a cure.

Chapter 6 deals with the magical treatment of disease, and Chapter 7 with treatments that are partly rational and partly magical. "There is", says Dr. Harley, "no assurance that any particular remedy is used for its drug content, and not for some fanciful resemblance of leaf, seed, flower or thorn to the lesion of the organ which is the seat of disease. . . . Yet there is no doubt that most of the remedies included under the discussion of rational treatment have therapeutic value." But some critics might consider that no sufficient evidence had been adduced to justify this wide generalization.

The succeeding chapters deal with the treatment of snake bite, the Snake Society known as Ba Kona, and the Poro Society which is largely a 'medicine' society. There is a great deal of new information in these chapters. The treatment for snake bite is difficult to evaluate, being a mixture of the rational and the magical. Even the piece of bark tied above the wound would appear to be doubtfully described as a 'tourniquet', since it seems to be regarded as a 'ring' for warding off evil. It is said that members of the Snake Society catch and tame any kind of snake except the spitting cobra.

There is an interesting chapter on black magic and poison, and another on divination. The method of manipulating the well-known ordeal of boiling oil is explained. If the accused was to be found innocent, some water was added to the oil, the water stayed at the bottom of the pot and boiled first, giving the appearance of boiling to the oil while it was, in fact, still comparatively cool.

In his summary of diseases showing types of treatment differentiated as 'rational', 'magical' and 'mixed', Dr. Harley estimates that 65 per cent of the diseases have treatments which are clearly rational. Only thirteen out of ninety-nine diseases are lacking in any indication of at least partly rational treatment. But the system of classification is scarcely scientific, since many of the native names for diseases are merely rough descriptive phrases. It cannot be supposed, for example, that there are special native treatments for 'liver abscess' or 'malnutrition'.

The book concludes with a valuable supplementary chapter on native medical practice in Africa as a whole, and there are also a bibliography and a botanical list of the plants mentioned in the text. The bibliography omits a number of books which Dr. Harley could have used to advantage. Meek's "A Sudanese Kingdom", for example, should have been included, as this contains an entire chapter devoted to medicine and witchcraft among the Jukun of Nigeria, who appear to have a great deal in common with the Mano and even to share some of their terms. Another noteworthy omission from Dr. Harley's work is any discussion of the phenomenon so characteristic of West Africa, namely, 'possession'.

These criticisms do not alter the fact that Dr. Harley has provided a first-rate text-book on native African medicine.

THERMODYNAMICS AND CHEMICAL ENGINEERING

Thermochemical Calculations

By Dr. Ralph R. Wenner. Pp. xii+384. (New York and London: McGraw-Hill Book Co., Inc., 1941.) 28*s*.

THE application of the concept of equilibrium to industrial processes involving gaseous reactions and changes of state has met with such success as to encourage a more extended use of the thermodynamic method in other directions, and numerous attempts to do so have been recorded in the literature in recent years. A great deal of ingenuity has been expended in overcoming some of the more obvious limitations of the method; for, apart from the lack of essential data, there are difficulties of a fundamental kind due to the fact that no 'real' system is in true equilibrium with respect to all the possible changes which may occur within it; and industrial processes generally include a time factor which is not taken into account in the thermodynamic treatment.

It can be seen, therefore, that Dr. Wenner has set himself a formidable task when he undertakes to satisfy the investigator who, "attacking problems of pure and applied science, seeks the specific thermodynamic methods which are applicable to his problem and the data requisite for its solution". It is only fair to say that he succeeds better than might have been expected. The reader may regret certain important omissions from the theoretical part of the book and he will recognize the practical difficulties which have led the author, on occasions, to adopt procedures which, at best, must be regarded as dubious. But he will also pay tribute to the care which has been taken in the selection and working out of problems illustrating unit processes in nearly every branch of chemical technology.

The notation and theoretical treatment employed throughout the book are those familiar to American students. The fundamental thermodynamic quantities chosen are the "characteristic function"—total energy, with the independent variables, entropy, volume and chemical content; the remaining functions are then expressed in terms of the characteristic function and its differential coefficients with respect to the three variables. The earlier chapters deal with the thermal effects accompanying changes of state, solution processes and chemical reactions and with equilibria.

One of the essential requirements in applying the thermodynamic method is to be able to predict with some certainty changes in the values of the appropriate functions over a wide range of experimental conditions. In most instances this may be done from a knowledge of the heat capacities of the components of specific systems between the absolute zero and the working temperature, the enthalpy changes associated with any changes of state occurring between these two temperatures and the heat of formation of each component at some stated temperature.

The significance of these changes, particularly in systems of more than one phase, is by no means obvious from tabulated data, and simple graphical representation is to be recommended wherever possible. It is to be regretted that Dr. Wenner neglects this method. In the chapter on the liquefaction of gases, for example, processes of refrigeration, compression and expansion are worked out by the aid of thermodynamic relationships and formulæ, which are cumbersome to use and fail to give any clear picture of what is happening. The construction of the relevant thermodynamic diagrams, on the other hand, is not difficult and constitutes a most instructive exercise for students; it merely consists in selecting any two of the variables p, T, H, S and V as co-ordinates and plotting a series of curves along which the other properties remain constant. It is immaterial which pair is chosen since, in principle, all such diagrams are equivalent, but for general purposes the (H,T), (T,S) and (H,S) diagrams are the most convenient. Data for most industrial gases are usually available or may be calculated with sufficient accuracy by well-known methods.

In dealing with physical and chemical equilibria methods based upon the concepts of 'fugacity' and 'activity coefficient' are employed. These quantities are evaluated from experimental data or from an appropriate equation of state. In recent years redeterminations of the compressibilities of all the more commonly employed gases and vapours have been carried out with a degree of accuracy sufficient to permit of the graphical computation of such derivatives as $(dv/dp)_T$, $(dv/dT)_p$ and $(d^2v/dT^2)_p$. The isothermal data may be expressed by empirical series equations in which the product pv is developed in terms of powers of p with the requisite number of constants to cover the whole range of the experimental observations, or by semi-empirical equations of state in which the constants are fewer in number and can be assigned some kind of physical meaning. Dr. Wenner favours the latter; but there is little to choose between the two types, provided always it is understood that they are valid only over restricted ranges of temperature and pressure. Where no experimental data are available, the law of corresponding states (based upon an equation with two constants) can be used to give a rough estimate of compressibilities.

From a knowledge of the sign and magnitude of the free energy and entropy changes resulting from a specific process carried to completion, and the corresponding figures for any secondary processes which may occur simultaneously within the reacting system, it is possible to fix within reasonable limits the temperature and pressure likely to favour the change it is desired to bring about. In this connexion two chapters are devoted to indirect methods of estimating free energies and entropies based upon the Third Law and upon the statistical interpretation of entropy.

The chemical engineer, however, has not only to assure himself of the thermodynamic possibility of such a process, but also to decide whether the physical or chemical changes involved in it can be made to proceed at measurable and useful rates under practical working conditions. As already mentioned, thermodynamics fails to give a conclusive answer to this question; but it does afford indications which enable a forecast to be made of the factors most likely to influence the result in the desired direction.

As Dr. Wenner rightly points out, there is scarcely any instance in which the complete elimination of the preliminary thermodynamic analysis of a problem in chemical technology can be justified by the absence of essential data; and he emphasizes this view by suggesting wherever possible alternative indirect methods of computing thermodynamic functions from molecular structure, spectroscopic and other physical data.

The book concludes with a section containing some sixty unsolved problems suitable as class-room exercises.

D. M. NEWITT.

'NEW LAMPS FOR OLD

What the Future Demands of Religion

By R. F. Delancey Wellbye. Pp. ix+182. (London: Watts and Co., Ltd., 1942.) 5s. net.

THE question which Mr. Delancey Wellbye sets at the beginning of his book, and answers in the affirmative, is this: "If God and an after life are set aside as probably unprovable but anyhow irrelevant to the conduct of this life, and if the miraculous is discarded as incredible and needless, do the elements of a satisfying and sustaining religion exist?"

Mr. Wellbye finds such a satisfying and sustaining faith in an evolutionary philosophy, for which the universe, and especially our world, is 'intensely dynamic', and for which the human individual, caught up in the cosmic drive, is the growing-point of progress. Man is part and parcel of the creative evolutionary process, its agent as well as its offspring, fulfilling his nature by co-operating with it. Man's nature is fourfold: he is a creature that (1) reflects, (2) feels himself to be a 'self' with an inner life that matters more to him than the outside world, (3) is co-operative and friendly by nature, and (4) has a personality which is not something given or fated, but continually enriched and changed by absorbing experiences. It is by developing these various potentialities that man enriches his personality and so becomes actually the dominant form of cosmic activity. Mr. Wellbye claims that "This vision of a universe in action, and of man within it, its agent and destined in all likelihood to become the dominant form of cosmic activity on this planet—this is a vision by which man can live, finding life good, and proud in the faith that human and cosmic destiny entwine".

Such being Mr. Wellbye's philosophy, his ethic is realistic. Goodness is appropriate action—action naturally taken if the circumstances are envisaged as they actually are, and not simply as they appear to a vision limited and distorted by self-interest. If conduct is based on valuations or estimates of fact which are false, disaster inevitably follows, for successful action proceeds from a proper adjustment to reality. Thus desire has to be revised and corrected in the light of understanding, which is defined as "the ability to see through the meaningless world of appearance to the significant world as it is in relation to human activity". Thus Mr. Wellbye's scheme of things gives an absorbing purpose to human life and bases conduct upon an understanding of reality.

It will be seen that the view of humanity outlined in these pages is a favourable one, and this in spite of the strong temptation which present circumstances offer to take a contrary view. Unfortunately, much orthodox religious apologetic is now taking the pessimistic point of view, which is also the obvious one. Mr. Wellbye does not base his views on mere sentimentalism but on the anthropological researches which have exploded the popular myth that primitive man was a savage cave-dwelling individualist, but established him rather as a kindly co-operative creature, who had to be educated in cruelty by civilization. That our own civilization educates us in egoism can scarcely be denied. If institutions are the product of man, it is no less true that man is also the product of his institutions.

Mr. Wellbye, though one can sympathize with his motives, is possibly less than fair to the traditional religious point of view; for example, we doubt if any instructed Christian would really hold "that what is good and what is wicked in human conduct rest finally on the arbitrary will of God". He would be much more likely to say with Mr. Wellbye himself that morality is behaving in accordance with the nature of things, about which there is certainly nothing arbitrary. Nor is it historically true that "the Christian Church has invented the category of sin". Sin is indeed a specifically religious and not merely a moral conception, but it is one which was widespread in the pre-Christian period, as the works of Prof. Angus, whom Mr. Wellbye names in his bibliography, show. The fact that the idea has been over-stressed does not divest it of truth. Mr. Wellbye emphasizes the importance of sensitiveness as a means of enriching personality; and the absence of all 'sense of sin' is a form of moral insensitiveness. It is not only physical ills, such as a toothache, that make a normal man feel uncomfortable. Mr. Wellbye also speaks of the capacity to absorb and use our experiences so that they change us; one of the positive achievements of the traditional religion has been that it has enabled people to convert adverse and disagreeable experiences into a means of enriching life and endowing it with new graces. There are those who, "going through the vale of misery use it as a well, and the pools are filled with water". Too many critics of the traditional religion have failed to recognize that it has satisfied a far larger variety of human needs than has any *ad hoc* system of ideas. Christianity is a pool where elephants may swim as well as lambs drink, and seems a different place to either. Perhaps Renan was not far wrong in saying that few people have the right to disbelieve in it.

The fact is that the constructive half of Mr. Wellbye's book is better than the critical half; and that is a good deal more than can usually be said of books of this character. His attempt to outline a new way of looking at things (which is perhaps not so new after all) is vigorous and stimulating.

J. C. HARDWICK.

HIGHER ALGEBRA

The Tutorial Algebra

By Dr. William Briggs and Prof. G. H. Bryan. Revised and rewritten by Dr. George Walker. Vol. 2: Advanced Course. Fifth edition, revised and rewritten. Pp. viii+599. (London: University Tutorial Press, Ltd., 1942.) 12*s.* 6*d.*

THE first volume of this standard work, published in 1940 in a revised and rewritten form, covered the algebra prescribed chiefly for the intermediate examinations of the University of London. The present book takes the work to a higher stage, and this additional volume was rendered necessary owing to the rapid expansion of the subject and, therefore, the need for the incorporation of a large quantity of new matter.

Volume 2 carries the course from infinite sequences and series to the theory of equations. The more advanced algebra required for London Intermediate Economics Examination and by students preparing for the several Higher School Certificate examinations is thus adequately provided in 542 well-filled pages of clearly written text. The binomial theorem, the exponential and logarithmic series, convergency, complex numbers, recurring series, summation, determinants, elimination and the theory of equations are all dealt with in a rigorous, comprehensive and skilful manner. The principles developed are excellently illustrated by aptly chosen examples, and the methods of solution are, in general, models of conciseness and elegance.

Indeed, in so many ways is the treatment so good that even more would seem to be desirable. This is particularly the case in the consideration of the biquadratic, although reference for more detailed discussion is given on p. 508. From a practical point of view, the quartic equation is becoming of increasing importance; yet rarely is a complete analysis of it to be found. It is therefore somewhat disappointing to find that no real development of the discriminant of the quartic, like the corresponding treatment of the cubic, is included in this valuable book. Incidentally, example (2) on p. 510 appears to require some clarification. Is the condition $ac-b^2>0$ sufficient to indicate the presence of at least two imaginary roots in a given biquadratic? The equation, $x^4-4x^3-35x^2+122x-168=0$, has two real roots, -6, 7, and two imaginary roots, $\frac{1}{2}(3\pm i\sqrt{7})$; yet $ac-b^2$ is negative.

Only one other point need be mentioned: this concerns the determinantal equation on p. 511 which yields the reducing cubic in $\lambda\lambda'$. As the text reads, the student is given no hint that this equation is the eliminant of the separate coefficients, λ, λ', μ, μ', after each of these has been expressed in terms of the unknown $\lambda\lambda'$.

However, apart from these points and the few misprints noticeable, the revised edition of this work can be confidently recommended as a thoroughly good and sound course in modern algebra.

F. G. W. BROWN.

Handbook of Technical Instruction for Wireless Telegraphists

By H. M. Dowsett and L. E. Q. Walker. Seventh edition, extensively revised and enlarged. Pp. xx+664. (London: Iliffe and Sons, Ltd., 1942.) 25s. net.

IN such a rapidly-growing subject as radio communication, a technical book which has survived to a seventh edition must first have possessed a very sound basis in its original form, and secondly it must have been very wisely kept abreast of the subject by its authors. All wireless operators of the pre-1914 vintage will remember the first edition by J. C. Hawkhead; this book was a standard work of its time for all would-be operators studying to qualify for the Postmaster-General's certificate. The latest edition maintains the traditions of its forerunners in providing for operators and engineers a complete course of instruction in the general principles and practice of marine wireless communication.

The work has been brought as fully up to date as is possible in a field that is not infrequently disturbed by novel applications of a somewhat revolutionary nature. It deals with the whole range of a ship's communication equipment from the power supply to the transmitting aerial, and from the crystal detector or valve receiver in a small ship to the elaborate loud-speaker installation and public address system in a luxury liner. The technical treatment also covers such aids to navigation as direction finding, depth sounding and distress call apparatus. One of the main features of the book is the large amount of photographic and circuit diagrammatic material given on all types of commercial radio-marine equipment in use at the present time. In view of the somewhat long life possessed by some of this equipment, the authors appear to have overcome successfully the difficult task of replacing obsolete material by descriptions of current designs, without making the resulting book unduly large.

The volume may be thoroughly recommended to all who are concerned with marine radio communication, not only to assist them to pass their qualifying examinations, but also as a work of reference during their active careers.

A Check-List of British Birds

With a Short Account of the Status of Each. Revised edition. Compiled from "The Handbook of British Birds". By H. F. Witherby. Pp. 78. (London: H. F. and G. Witherby, Ltd., 1941.) 5s. net.

AS a companion to the "Handbook of British Birds" (five volumes), the small but valuable "Check-List of British Birds" has just recently been prepared by Mr. H. F. Witherby. This list of British birds is reprinted from the "Handbook": it is set down in the briefest possible form; for fuller particulars the "Handbook" itself must be consulted. No fewer than 424 species of birds have been admitted to the British list; of these, 219 species have bred in Britain during the present century.

The "Check-List" is clearly printed, on excellent paper, and will prove a valuable addition to the list of ornithological publications.

On p. 42 is a printer's error which may perhaps be altered in a future edition. Here it is stated that the osprey last bred in Scotland in 1902. For 1902, the year 1908 should be substituted. The last accepted nesting of the osprey in Scotland (although there is a possibility that the species has bred later) was in the year 1908, on Loch Arkaig in Inverness-shire. Cameron of Lochiel, on whose property these ospreys nested, writes to me as follows: "The Ospreys nested on Loch Arkaig in 1908. One solitary bird returned for five years afterwards, and was last seen in 1913. I believe this bird was shot in Ireland, as I myself saw a stuffed osprey in the south of Ireland, and was told that the bird had been shot in 1913. In 1907 there were three young birds in the Loch Arkaig eyrie. In 1908 the eggs were stolen."

Ospreys still visit the Highlands of Scotland on migration, and it is possible that one year a pair will remain to nest in some tree or ancient castle of an ancestral loch. SETON GORDON.

Short Wave Wireless Communication

Including Ultra-Short Waves. By A. W. Ladner and C. R. Stoner. Fourth edition, revised and enlarged. Pp. xv+573. (London: Chapman and Hall, Ltd., 1942.) 35s. net.

THIS now well-known technical book was first published about ten years ago, and the fact that a fourth edition has become necessary shows that its popularity is being well maintained among the constantly increasing number of radio communication engineers and physicists. A notice of the third edition appeared in NATURE of November 14, 1936, and it is noted with some satisfaction that the opportunity has now been taken to re-arrange the chapters in a more suitable manner.

In so far as the censor will permit, the whole work has been revised and brought up to date to form a comprehensive treatise on the technical principles and application of radio telegraphic and telephonic communication on wave-lengths less than about 100 metres. A chapter entitled "Electron Oscillators" contains much new material on the various types of oscillators available for the ultra-short wave-lengths less than 10 metres. A new chapter deals with high-frequency therapeutic apparatus, and attempts to present in a clear manner the facts, as well as the very controversial claims, covering the application of high-frequency radio apparatus to medical treatment.

This new edition of the book deserves to have continued success.

Brompton Hospital Reports

A Collection of Papers recently Published from the Hospital. Vol. 10, 1941. Pp. vii+127+29 plates. (London: Brompton Hospital, 1942.) 5s. net.

WITH the exception of a paper on the "Persistence of Lipiodol in the Lungs after Bronchography" all the articles in these reports, of which Dr. Maurice Davidson has succeeded the late Dr. Bosanquet as editor, have previously been published in various medical periodicals. Three of the ten articles are of special interest at the present time, as they are devoted to chest surgery in war, while the rest deal with the etiology of subacute pulmonary infections and erythema nodosum, the medical aspects of chronic empyema and tumours of the lungs. An authors' index to the first ten volumes, a subject index to the first nine volumes, and a subject index to the present volume are appended.

FUTURE OF THE MILK INDUSTRY*

By PROF. H. D. KAY, O.B.E.
Director of the National Institute for Research in Dairying

THE future of the milk industry in Great Britain is the key to two matters of extraordinary national importance. Its future is, by and large, the future of national nutrition ; its future is, no less, the future of British farming. An expanding milk industry is our best guarantee of a steady improvement in the health and physique of the rising generation ; a declining milk industry would foreshadow the rapid re-entry of British farming into the Slough of Despond. The future of the industry is not a thing to be regarded as starting after the War. It is starting now, and developments taking place to-day and during the War are influencing and shaping it continually. In fact, the War is catalysing valuable changes in the industry which might otherwise have taken years to accomplish, though slowing up other desirable developments that some of us had hoped to see before now.

The milk industry includes what is, in terms of money value, nutritional significance and numbers engaged, the greatest of our agricultural enterprises, that of dairy farming (having at the present time a turnover of some £100 millions a year), together with one of our major home industries, that of milk processing and distribution (having a turnover of some £150 millions a year). Technically, administratively and educationally, this large industry must in the future be regarded as one unit. For present purposes I shall not consider the closely related industries of cheese, butter and ice-cream manufacture, or the large ancillary trades concerned with the preparation of cattle feeding-stuffs.

Need for Planning

Freedom from want entails forethought. Our cave-dwelling ancestors, rugged individualists all of them, may have spent a happy summer and autumn under the greenwood tree and fairly full of food, but their winters must have been extremely thin and meagre before they began systematically to plan their food supplies ahead and to till the soil.

The major half of agriculture—and by agriculture I mean continuous agriculture and not the crop snatching that has terminated in certain parts of the world in complete loss of fertility, or even in loss of the soil itself by erosion—is forethought and planning, planning not for a year, but for several years ahead. The producing side of the milk industry, founded on the all-the-year-round consumption of agricultural products by livestock, is an activity where careful planning ahead is particularly important. The matings occurring this spring are laying the foundations not merely for next winter's milk production but also for our milk supply in 1945. The education that we are giving—or not giving—our potential dairy farmers to-day is securing efficiency or piling up trouble for the 1950's and 60's. Unless we are completely dead to all the lessons which peace ought to have taught us and which the War is daily and rather painfully underlining, we must all be agreed that one of the fixed points for any post-war milk industry is that it must be organized as a unit.

Objectives of the Milk Industry

A planned system must have an objective. The primary function of the milk industry is now, and will continue to be after the War, to produce and distribute effectively, to all human beings who need it, when and where, and in what quantities they need it, and in the highest possible quality, a key foodstuff that is essential in certain stages of human life and of major value at any stage. Its secondary function, requisite for the performance of the first, is to provide a reasonable living for those engaged in the industry. The acceptance of this view with its stress on the meeting of human nutritional needs as the primary object of the milk industry means a fundamental change in the habits of thought of some of us, and has many implications which I cannot pursue now. One assumption, however, I must make, that any future Government of Great Britain will take over the mantle which the present Government is, I think, the first effectively to wear, in insisting that the steady improvement of the health and physique of the people, particularly of the rising generation, and the promotion of British agriculture, are two of their main and closely interlocked duties. Milk is central in both of these.

We are in the fortunate position that we can *now* give to the industry a fairly close estimate of our future national needs. As a result of a large body of experiments and surveys extending over the past twenty-five years we now know sufficiently well what is the average quantity of milk per head of the population that is needed for adequate nutrition, that is, needed to raise the nutritional level of our people to that at which optimal physical growth and development and general health (so far as they depend on nutrition) may be attained. It is not less than 0·8 pint per head per day, probably not less than 1·0 pint. At present our average consumption is just over 0·4 pint per head per day. This figure is slightly greater than the amount in Great Britain in pre-war days, but slightly less than that consumed in the very poorest of American cities.

On a yearly gallonage basis, 0·8 pint per head—taking the lower of the figures just mentioned—means 1,650 million gallons a year. Liquid consumption is evenly distributed over the whole year, so that about 140 million gallons per month, winter and summer alike, will be needed. This means a 75 per cent increase in present *winter* milk production, though only a 30 per cent increase in summer production, assuming practically no milk for manufacture.

Two objections will rise to everyone's mind. First, will not the population, even if it has the money to buy the milk, slip back after the War into the peace-time habit of a low milk demand, so that any increase in production will merely mean more to be manufactured ? The second question is, will not the post-war home dairy farming industry and the purchasing power of our population both be too severely hit by war impoverishment to hope to attain anything approaching this level of supply or demand ? My reply is that it would be most unwise to underestimate the speed of recovery both in general economic level and in agricultural developments of an adequately mechanized civilization like our own provided we win the War, and provided we manage to canalize, in a socially positive direction both the enormous industrial forces and the great psychological drive that will be liberated when peace is declared.

---

* Substance of a paper read before the Royal Society of Arts on May 20.

Could any part of these requirements be met by the importation of dried or condensed milk? Undoubtedly, but in relatively small part. To provide a year's supply some 800,000 tons of dried milk would be needed. The Southern Dominions, working all out on milk drying, might provide one-twentieth of this amount. Even if dried milk in the necessary quantity, flavour and ease of reconstitution could be imported, a good deal of persuasion would, in my opinion, be needed before it could be used in the household on any impressive scale. In bread and confectionery making, in the institute, canteen or restaurant, dried milk could readily be used to the limits of any visible or likely supply.

Increased Efficiency of Dairy Farming

To meet the liquid milk demands I have just envisaged, most dairy farmers in these not very large islands will have to increase their efficiency and improve their management very considerably.

The yield of milk per cow per year offers a wide field for improvement. From the 520–550 gallons of the pre-war years (now down to about 460) it could be raised in a decade or so by the use of knowledge we already possess (perhaps most rapidly by taking every advantage of artificial insemination from first-class sires) to 700–750 gallons. That this is a reasonable estimate of what can be done is supported by the fact that the yield per cow in Denmark some ten years ago was officially stated to be 704 gallons per cow. Further, by control, much of which is now possible, of sterility and other bovine diseases, the average length of milking life of a cow, now less than four lactations, could be steadily raised to six, seven or even more. Instead of being a very rare creature, the 5,000-gallon cow (that is, an average of about 700 gallons for seven lactations) would be found in most herds. To enable this objective to be more rapidly reached, not only must existing knowledge be rigorously applied, but also research in the control of cattle diseases, and particularly the physiological and pathological study of bovine sterility, pressed forward with renewed energy when some of our more immediate war tasks are ended.

We shall have to control more carefully the type of bull to be used in dairy herds. Any future scheme for the use of better sires will undoubtedly receive the hearty support of the milk-producing industry. It is of interest to remember that the Ministry scheme for licensing bulls, which was rather unwisely allowed to lapse at the outbreak of war, was put into action again at the urgent request of the farmers themselves. The use of any bull inferior to the son of a proved sire out of a high-yielding dam ought, in fact, to be increasingly discouraged in the future in any herd pretending to be a dairy herd. In addition, a simple system of milk recording, without which no dairy farmer can effectively plan his feeding, breeding or culling programme, will have to be made, if not universal, as near universal as makes no matter.

Present milk shortage is due as much to lack of knowledge as to lack of feeding stuffs. Next winter's milk production, as well as that in the post-war future to which I have been referring, depends largely on the more general practice of modern—which are at the same time economical—methods of feeding. It is to be noted that per unit of feeding-stuff consumed, the 700-gallon cow is much more efficient than the 500 galloner.

After the War, if we are able to return to, and to pay for, the importation of sufficient animal feeding-stuffs, the solution of the milk producer's winter feeding problem will be relatively easy. In any case we shall probably have to continue in part on the fundamentally sounder lines along which the War has driven us—the production of *better-quality protein-rich* feeding-stuffs at home. Of these, the major ones for milk production are still good leafy grass during the growing season, which will, in the future, be extended on the average by a fortnight at each end, hay cut at a relatively early stage with as much clover in it as possible, and well-made silage from young grass or from an oats and pulse mixture. Young grass and grass products will probably continue for some years to be our main protein-containing foodstuffs for the dairy herd, and the basic knowledge that has been acquired in the last two decades as to how to improve productivity and stock-carrying capacity of grassland should enable us to meet increasing demands for the milk-production ration without encroaching too severely on other types of farming or upsetting farming balance.

Increase in Cow Population

Even if we succeed in increasing the average yield per cow from the pre-war 520–550 up to 700–750 gallons, it will only give us about 40 per cent of the increase in milk production that we require to meet human nutritional needs. In addition to increased individual yield, there will also have to be an increased dairy herd. From the present population of a little more than 3,200,000 cows and heifers in milk and in calf, it will have to increase to nearly 4½ millions.

As a result of improvements in grassland and grassland management, better knowledge of arable cropping for milk production, increasing soil fertility as the manurial output of the increasing herd steadily rises, and as artificial fertilizers are used with greater skill, this population should require little more dairy-farming acreage than does the present relatively inefficient herd.

The more the farm is self-supporting as regards cattle feeding-stuffs, the more is it necessary to put back into the soil those minerals inevitably lost in every gallon of milk leaving the farm. Concomitant with an increased milk output is, therefore, an increased requirement for lime, for basic slag and other phosphatic manures, for potash and for nitrogen.

Larger Dairying Units

Not only will there be in the future a larger population of dairy cows per 100 acres, but the average dairy-farming unit will also increase very considerably in acreage, with a decrease in the total number of holdings. The average dairy-farming unit at present is only some 12–14 cows strong, but the greater efficiency of a larger unit, where both general and specialist machines can be used to advantage, overheads spread over a larger acreage, cropping policy planned on a wider basis, disease control managed more effectively, purchases made on more economical terms, better arrangements made as regards hours of work, holiday periods and so on, needs no emphasis. It is repeatedly stated that dairy farming is a particularly onerous job. This is true while the units remain small. But with a larger unit, say one having not less than 40–50 cows in milk, where three or four men or more may be available for cow-shed work, a little organization should make it possible for the duties of feeding, milking and day-to-day operations generally to be scarcely more onerous than those on any other type of farm.

Chartered Dairy Farmers

An organized and planned milk industry may demand in the not too distant future standards of professional competence before would-be entrants into dairy farming are allowed to use land at all. It may also insist on the squeezing out into some other avocation in which he will do less harm, of the incorrigibly dirty and inefficient milk producer. Modern dairy farming demands, in no small measure, relatively new knowledge which should be a minimum asset of any who hopes to have the privilege of using a portion of our limited farming area to the best national advantage. The idea of the chartered dairy farmer is not so visionary as it sounds. Meanwhile, until vocational farming education on modern lines —which means, of course, no educational stunt, but the combination of new knowledge with ripe and tested experience in an organized course of training —can be extended to cover the needs of the large majority of new entrants into the farming profession (instead of only about 10 per cent of them as at present) the appointment in all our dairying counties of competent dairy husbandry advisers is highly desirable.

Improved Quality of Milk

The future of milk quality has three aspects: that concerned with ordinary hygiene and cleanliness, that concerned with udder disease, and that concerned with compositional or nutritional quality. All these are closely linked up.

As regards cleanliness of production, absence of which leads, particularly in summer, to taints and souring, perhaps 50 per cent of farmers, mainly those who have been producing milk for some time and have learned the simple routine for avoiding contamination, turn out a consistently satisfactory article. As regards udder diseases, methods are now known for controlling the most important of these, streptococcal mastitis, and the national veterinary medical plan which is being put into practice on a voluntary basis should, if combined with an increase of the farmer's knowledge as to the simple methods he can himself use in the cow-shed to limit its spread, be of great assistance in diminishing the heavy toll of this disease on the quantity and the nutritional quality of our milk supply. As regards *compositional* quality of milk, practically no official attention has ever been given in Great Britain to the poor nutritional value of much of our market milk, to the great changes in its nutritive quality that may be brought about by changes in the nutrition of the cow, or as a result of chronic udder disease.

Disease

I have just mentioned one of the directions in which bovine disease affects the dairy farmer. Disease puts a gratuitous tax of at least 25 per cent on to the economic cost of every gallon of milk. Diseases, like tuberculosis and contagious abortion, which can cause human infection if the milk containing the organisms is consumed, are far less important from the consumer's point of view now that more milk is pasteurized, but are extremely important from the point of view of the dairy farmer, since they may easily ruin a first-class herd unless early recognized and checked. Some form of obligatory national veterinary health insurance seems likely in the fairly near future, together with an efficient State system of preventive veterinary medicine.

Distribution

Assuming that milk of satisfactory compositional, hygienic and keeping quality has been produced by our future dairy farmer, let us consider the next steps. He will either deliver it himself to the buyer, or more usually have the churns called for either at his farm or at some convenient place on the roadside, by the collecting lorry attached to the local collecting depot or distributing dairy. In the future the churns will contain cooled milk, well below 65° F. when they leave the farm, and will be placed, if they have to wait for a while, on a properly constructed platform with a light roof over it to protect the churns from direct summer sunshine. Transport rounds will be arranged so that such waiting is minimal. The lorries will leave clean and sterile churns on the platform, and take away the full churns to reach the collecting depot without delay. Here samples of milk will be systematically taken for the determination by quick, modern methods of compositional and keeping quality by a skilled tester working under a centrally organized and controlled milk quality scheme. On his findings fitting payment to the producer will be made. No milk, even that of poorest quality, will be returned to the producer. It will be appropriately salvaged. Slightly better milk which is of insufficient quality for the liquid milk market may be used for other purposes. The satisfactory milk will then either be brine-cooled or, better, pasteurized by the H.T.S.T. process before being sent forward immediately by rail, road, tank or churn to the distributing dairy.

In the very near future the waste of milk due to souring, which last summer reached a magnitude little short of scandalous, must be prevented. Methods for the prevention of souring, even in hot weather, have been thoroughly well worked out and are well known to many, perhaps half our dairy farmers, collecting-depots or creameries, and milk distributors. In the near future, every dairy farmer whose milk consistently fails to reach the necessary standard will be instructed on his farm by the county advisory staff on points of major importance, such as the adequate cleansing and sterilization of farm utensils, milking equipment and churns, and on methods for cooling the milk to below 65° F. and keeping it cool. Hot weather provides in an almost literal sense an acid test of efficient milk production and handling, and the milk industry of the future will be ashamed of its technical inefficiency if souring or taint production continues to occur every time there is a hot spell.

Collecting depots and distributors in trouble will similarly be assisted by the provincial dairy bacteriologist. The producer is by no means always responsible if summer souring occurs. Faulty churn washing, too prolonged transport rounds, or some other factor not within his control may be to blame.

Pasteurization Requirements

The pasteurization bogey which has caused so much controversy and even ill-feeling in the past is now satisfactorily laid. Careful scientific experiment extending over some years has recently shown, and all those competent to assess the clear-cut evidence now agree, that properly controlled commercial pasteurization causes practically no nutritional damage to milk. In the near future it will almost certainly be a national requirement that all milk sold for liquid consumption shall either be effectively pasteurized, or shall be from disease-free animals. The methods of pasteurization which will be used for the majority of town supplies after the War will undoubtedly be the H.T.S.T. process, recently officially accepted, which offers considerable technical advantages besides requiring far less space and metal than the old 'holder' process.

A beneficial consequence of such a national requirement is that many of the dirtier milk-handling and distributing premises will have to shut down. This will save a good deal of the unnecessary and wasteful duplication of milk rounds that still persists even under present war-time conditions. It is quite absurd that in a town of 100,000 inhabitants there should be no fewer than 200 licensed distributors of milk, many of them working from domestic kitchens and back-yards under indescribable conditions. Ten distributing units, adequately staffed and hygienically equipped, could do the job far more satisfactorily. Whether compulsory pasteurization is introduced or not, careful re-inspection of all licensed milk distribution premises is urgently needed in the immediate future, with revocation of licence where ordinary conditions of decency are unattainable.

The milk-distributing, like the milk-producing side of the industry, suffers from having too many small, dirty and inefficient units. It also suffers, even to a greater extent that the milk-producing side, from a paucity—almost a complete absence—of organized technical and vocational training and advisory help. Modern milk distribution is not a robot operation which can be carried out by unintelligent and untrained personnel. One of the pressing needs of the immediate future is the organization of courses of technical training in processing and distribution of milk.

Education and Research

Any long-term view of the future of the milk industry must concern itself with (*a*) the general education, and (*b*) the vocational training of the dairy farmer, the milk distributor and manufacturer, and the housewife. The milk industry is founded on knowledge that is continually advancing and extending, and its future prosperity and ability to meet the demands which the nation will make on it will depend in large part on the rate with which new knowledge can be acquired, assimilated by the industry and effectively applied.

As regards the acquisition of new knowledge, the total number of workers dealing with the research problems of milk production, processing and distribution is very small, probably less than fifty for Great Britain. Compared with the magnitude of the industry, the extent to which it is based on scientific and technical knowledge, and the number and importance of the immediate problems, both fundamental and otherwise, that await solution, this number is almost incredibly small, able though the little handful may be, and until a year or so ago its financial resources were grossly inadequate.

One of the needs of the near future is increased facilities for semi-large-scale experiments, both on milk handling and processing problems, and in methods of milk production, with an adequate research staff to deal with them. (Research workers of the type I have in mind require from five to ten years of post-graduate training before they can tackle such problems adequately, and the training of such workers is in itself a problem which the paucity of dairy research facilities in the past has rendered acute.) At present there are in several cases only two alternatives: either to leave a piece of work at the laboratory stage of development and trust that some better equipped country or some private firm will take it up, or to endeavour to go direct from the laboratory to the full industrial scale through the good will, and at the risk of, a firm in the industry. This latter method, even at the best, inevitably involves lack of control of details, of labour and of management that may make the difference between success and failure.

For experimental work on the improvement of milk production, research facilities are still meagre. Experiments on an adequate scale in dairy husbandry and on the physiology of the dairy cow will need, in the future, the use of several large experimental herds under careful control, if they are to have a prospect of success within a reasonable time.

As regards the dissemination and practical assimilation into agriculture without too great a time-lag of the results of research, the recently founded Agricultural Improvement Council should be, both in the immediate future and after the War, of considerable benefit to the production side of the milk industry, and to a smaller degree to the handling and distributive side. The maintenance of adequate financial support for the activities of the Agricultural Research Council and the Agricultural Improvement Council, after the War, is a vital step towards securing a brighter future for the milk industry.

OPENCAST MINING

By PROF. J. A. S. RITSON, O.B.E.

Imperial College of Science and Technology

DURING recent months the provision of sufficient coal to meet the growing needs in Great Britain of the munition industry, as well as the domestic consumer, has been exercising the minds of the public and has been the subject of considerable discussion in the Press and both Houses of Parliament. Among the many suggestions for increasing the war-time output, the winning of coal by opencast methods has been mentioned. Opencast workings or opencuts are surface excavations in which the overburden is stripped by hand or mechanical excavators, thereby laying bare the mineral, which is afterwards broken and loaded into wagons or lorries by methods similar to those used for removing the overburden. In some localities in Great Britain the conditions are known to be suitable for the successful application of this method of working and intensive prospecting may result in the discovery of more. Several estimates of the total amount of coal available and also of the amount that can be extracted in the current year have been given wide publicity, but the facts, as so far proved, suggest these figures are optimistic.

The coal seams outcrop at the surface in nearly all the coalfields of Great Britain, but in the majority of cases they have already been worked by the 'old men' from bell-mouthed pits or else by gangs of miners during periods of industrial trouble, such as strikes or lockouts.

There is nothing new in the method, which has been practised since the early days of mining, and it is in common use in most parts of the world to-day. The brown coal of Silesia is worked this way, large quantities of bedded ironstone are produced from such operations in Great Britain itself, also ironstone in Austria, the United States and the Gold Coast, tin in Malaya and Nigeria; chrome in Turkey, coal in the United States, Australia and Bulgaria, copper in Chile and the United States. These are typical examples, which can be multiplied many-fold, of successful exploitation of the method.

In Great Britain the application of the method to coal has never before been tried, the reason being that much of the better quality coal close to the surface has already been worked by underground methods, and successful opencasting requires either a large force of cheap labour or the provision of heavy, costly, excavating machinery of various types, many of which have only become available in recent years. Such machinery has been most successfully applied to home ironstone mines where the quantity of ironstone is large and the mining conditions very suitable. The majority of the remaining available excavating plant is in the hands of public works contractors who, while skilled exponents of the art of removing ground, have had little or no experience of the much more difficult problem of selective excavation, which arises when two or more seams of coal are separated by comparatively thin layers of stone. Special machinery is needed to deal with such a problem and it is not usually readily available in Great Britain.

As a coal seam approaches the surface its quality deteriorates. The moisture content is increased and the coal substance oxidized, it becomes dull and friable and loses both its coking and gas-making properties. It resembles in many ways an inferior lignite or brown coal. A typical analysis from one outcrop showing the change in composition of the coal as the cover gets thicker is given below :

Sample	Moisture as obtained or received	Air-dried moisture	Ash	Volatile matter less moisture	Total sulphur	Cal. val. (B.Th.U. per lb.)		Carbon on ash-free dry coal	Hydrogen on ash-free dry coal
						As received	Air-dried coal		
1st strip	31	10·3	6·3	33·4	0·7	7,150	9,350	70·7	3·8
2nd strip	25	6·8	2·8	33·3	0·8	8,690	10,750	72·7	4·0
3rd strip	18	8·5	1·6	31·8	1·1	10,470	11,670	76·4	4·6
Normal seam	—	5·9	3·7	33·3	2·0	—	13,600	82·3	5·3

As a consequence of this deterioration, thorough prospecting of each site by boring or trial holes to prove the quality of the coal and, at the same time the nature of the overburden, should be undertaken before productive operations begin. Failure to undertake this preliminary investigation may result in disaster.

The nature of the overburden is important; it should not be too porous or too hard. Tough clay not containing too many large boulders makes the best top surface, and this should be underlain by an impervious shale which can be broken by the digger without the use of explosives. Harder rocks like massive sandstone may render an otherwise desirable site unworkable. Explosives often have to be used to shake the tougher rocks so that they can be removed by the excavators, but their use adds to the complexity of the operations.

An ideal site involves a horizontal seam of coal with overburden that can be stripped in one operation. Rarely, except in the United States, are these conditions found; certainly not in Great Britain. Here the conditions usually consist of a more or less horizontal seam with a gradually increasing overburden; that is, the seam outcrops on the side of a gently sloping hill or, alternatively, the seam dips away from the outcrop and the surface remains level.

The value of the product determines in peace-time the thickness of overburden that can be removed. With coal the ratio is of the order of 3 or 4 to 1; with ironstone the figure is larger. To-day in England 20–30 ft. of cover are being removed to recover 5 ft. of coal, whereas with ironstone as much as 70 ft. are taken. The general plan of operations consists of combinations of loosening, stripping and transporting of overburden and mineral. The combination selected depends upon the shape, size and depth of excavation, the type of mineral, the quantity and value, output required, the surface topography, the nature and inclination of the overlying strata. Output and method should be adjusted to the total value of the product, so as to secure a minimum cost of production, though this may be qualified in war-time if output is more important than cost.

Stripping may be completed before beginning mining, or stripping and mining may proceed simultaneously when a sufficient area has been uncovered to avoid interference between the two operations. The latter plan is the better as it reduces the initial expenditure before production begins. Stripping may be done in one or more stages, depending on the depth. The overburden must be disposed within reasonable distance to avoid haulage costs and double or treble handling at points where the dumps will not embarrass future operations. The usual procedure is to remove the overburden with mechanical shovels or drag-line excavators and lay it on barren ground behind the outcrop line. Sometimes mechanical scrapers remove the top soil and carry it away, so that when the land is reclaimed after the coal is extracted the top soil can be put back on top.

Frequently large excavators with buckets carrying 12 cu. yards at the end of an 80-ft. boom are used in the main excavation, while smaller 2-yard machines stack the excavated ground clear of the cut. After the overburden has been removed down to the top of the coal, the Americans use mechanically driven rotary brooms to clean off the remaining dirt. Then the coal is dug by small shovels of $\frac{3}{4}$–$1\frac{1}{2}$ cu. yards capacity and loaded on to conveyor belts, wagons, large or small, or into lorries, some of which have a capacity of 10 tons. These take the coal either direct to the consumer or to simple screens where it is graded into two or more sizes.

The first coal obtained, that under the thinnest cover, is usually of poor quality, friable and breaks into small pieces quite suitable for the modern mechanical chain grate boilers, but as the cover thickens the quality improves and the average size of the product increases, so that in order to obtain its full value it has to be graded into large, nuts and slack, each of which has a definite commercial use.

Ironstone workings are usually of a more permanent nature than coal projects; consequently much larger and therefore more efficient plant can be, and is, used. The actual cost of mining ironstone is remarkably low.

The average coal prospect so far exploited in Great Britain contains up to 250,000 tons of coal, its breadth is 60–100 yards and its length $\frac{1}{2}$–$\frac{3}{4}$ mile. The overburden increases from about 12 ft. at the outcrop to 40 ft., giving an average thickness of 25 ft. for a 4–5-ft. seam. One interesting operation is working both flanks of an anticline where there are five seams of coal totalling 30 ft. in all, and these are being pursued to a total depth of 70 ft.

The largest known deposit unfortunately lies under 25–30 ft. of peat in the centre of a low valley, which was once a marsh, and the surface has only recently been drained. The difficulties of dealing with waterlogged peat and water make the proposition at present unattractive. Other outcrops which have not been touched are situated in built-up areas, public parks or allotment gardens.

Many of the outcrops in Great Britain occur under land which is suitable for agricultural purposes and in such cases care has to be taken to disturb as small an area as possible. The top soil is removed first and laid on one side, then the overburden is removed and dumped behind the excavation. After the overburden has had time to settle, it is levelled by mechanical spreaders or 'bull-dozers', field drains are renewed and then the top soil is brought back and the whole re-levelled. Experience has shown that the land, though at a lower level, loses none of its fertility and in two to three years is under cultivation again.

In some instances in Great Britain, and particularly so in America, the overburden is only roughly levelled and then planted with conifers. Flourishing plantations of larch, Scotch fir and spruce can be seen in the ironstone area.

During war-time, land for opencast work can be requisitioned under the Defence Regulations and this is usually the simplest method to employ. But various questions of compensation have to be settled. The coal owner must be paid for the coal extracted from under his land and the purchase price is generally on a tonnage basis; the colliery company that has leased the right to work the coal from its owner wants compensation for loss of rights or potential profit; the surface owner, if the land is divorced from the mineral beneath, requires compensation for damage to his land, loss of rent and amenities, while the farmer is denied, for the time being, the opportunity of cultivating the area in question.

Another point that has to be settled is transport. In some instances the coal can be loaded into lorries and carried direct to the consumer, but in most cases the railway or canal has to be utilized. This means the provision of new sidings or loading stages or, alternatively, the adaptation of existing sidings to outside traffic.

In peace-time the practice will not offer any financial attraction to operators, but in war-time, when it is essential to produce every ton of coal, it is worth pursuing.

IS MUSCLE CONTRACTION ESSENTIALLY AN ENZYME-SUBSTRATE COMBINATION?

By DR. JOSEPH NEEDHAM, F.R.S., DR. ARNOŠT KLEINZELLER, MISS MARGARET MIALL, MRS. MARY DAINTY, DR. DOROTHY M. NEEDHAM and Dr. A. S. C. LAWRENCE
Biochemical Laboratory, Cambridge

ABOUT twelve months ago an account was given in NATURE of the striking action of adenylpyrophosphate upon the flow-birefringence and viscous properties of the globulin of muscle, myosin[1]. Since the dephosphorylation of adenylpyrophosphate is believed to be the immediate source of energy for contraction, and since, in the most recent work, it has proved impossible, in spite of serious efforts, to separate adenylpyrophosphatase activity from the protein myosin (Bailey[2], Needham[3], confirming the original work of Engelhardt and Ljubimova[4]), a continuation of this work seemed necessary. Having in the meantime made further progress in the study of the physico-chemical relations of adenylpyrophosphate and myosin, we desire to make the following further interim report.

The apparatus used was partly described in the previous note. It now consists of a small annular cell with rotating external cylinder, mounted on the stage of a polarizing microscope; and a co-axial viscosimeter with glass bottom permitting optical measurements of flow-birefringence. Three variables are observed: (*a*) the intensity of flow-birefringence itself; (*b*) the extent of the anomalous viscosity (that is, the fall of viscosity at low shear-rates); and (*c*) the relative viscosity, that is, the constant level to which the viscosity eventually falls as the shear-rate increases. The flow-birefringence and the anomalous viscosity of myosin solutions are, of course, taken to indicate that the particles are of considerable length.

Since the data in the literature on the physico-chemical properties of myosin, though numerous, are rather disjointed, we had to devote a good deal of time to the systematic examination of certain effects, as background for the interpretation of the action of adenylpyrophosphate on myosin. Thus we find that in passing from member to member of the Hofmeister series of cations at $0\cdot5M$ ($\mathrm{Li}^{\cdot}$, $\mathrm{Na}^{\cdot}$, $\mathrm{K}^{\cdot}$, $\mathrm{Rb}^{\cdot}$ and $\mathrm{Cs}^{\cdot}$), there is no change in the flow-birefringence (hereinafter written $\triangle$), and only slight effects on the relative viscosity (η). $\mathrm{NH}_4^{\cdot}$, however, decreases $\triangle$. The behaviour of these properties as a function of different salt molarities is very similar for $\mathrm{K}^{\cdot}$ and $\mathrm{Li}^{\cdot}$; $\triangle$ falls (for example, from $\triangle$ 60° at $0\cdot5M$ to $\triangle$ 20° at $3\cdot5M$); while η first falls to about $1\cdot0M$, and then rises. (A hump is often observed at salt concentrations varying between $0\cdot5$ and $1\cdot5M$, which explains certain results mentioned in the previous note, but requires further study on more purified preparations.) At the higher salt concentrations corresponding to the rising limb of the curve, the flow anomaly appears to be lost. The whole picture may therefore be interpreted either as one of progressive disaggregation, or the formation of larger, unoriented, tangles; the process ending in precipitation by salting-out. With divalent cations, such as $\mathrm{Ca}^{\cdot\cdot}$ and $\mathrm{Mg}^{\cdot\cdot}$, though the flow-birefringence ($\triangle$) falls steadily as their concentration rises up to $0\cdot5M$, the relative viscosity (η) on the contrary *rises*, continuously in the case of $\mathrm{Ca}^{\cdot\cdot}$, but reaching a maximum about $0{\cdot}1M$ and then declining in that of $Mg^{\cdot\cdot}$ (see Fig. 1 *a*).

In the Hofmeister series of anions at $0{\cdot}5M$, though SO_4'', Cl' and Br' have no effect either on Δ or η; I' and SCN' reduce Δ and exert extensive and complex effects on η.

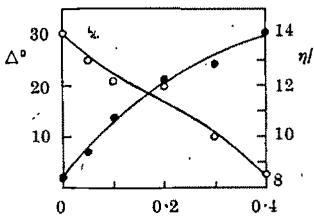

Fig. 1*a*.

The behaviour of myosin's Δ and η at different *p*H is interesting. Just above *p*H 5·5, as the protein comes into solution above its iso-electric point, both flow-birefringence and relative viscosity decline from high values to a constant level reached about *p*H 6·3, and this constant level is then maintained until *p*H 9·0, at which point the two properties begin to diverge. Flow-birefringence falls off to reach zero about *p*H 11·0 and relative viscosity climbs to values as high as they were just above the iso-electric point (see Fig. 1 *b*). Falling birefringence with loss of anomaly and rising relative viscosity may be interpreted as disaggregation or tangle-formation perhaps accompanied by hydration.

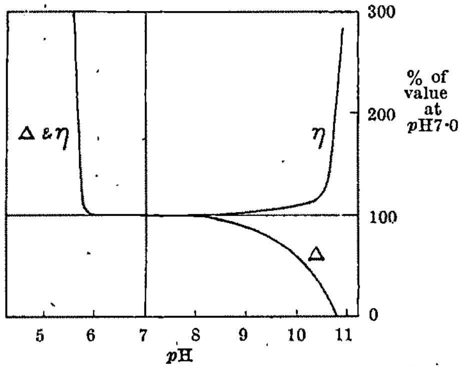

Fig. 1*b*.

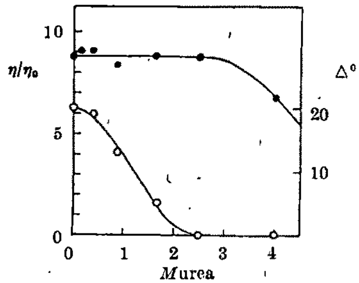

Fig. 1*c*.

Finally, with urea, in increasing concentrations up to 7 or 8 *M*, the relative viscosity, as shown by Edsall and Mehl[5], falls off to low levels. But during the range over which the flow-birefringence is falling to zero, the relative viscosity remains constant, that is, up to about $2{\cdot}5M$ (see Fig. 1 *c*).

The conception generally prevailing (see Edsall[6]), that decreases in flow-birefringence of myosin are irreversible and imply denaturation, must now be abandoned. After the action of adenylpyrophosphate, Δ invariably returns to its initial value; and if samples of myosin the flow-birefringence of which has been reduced by various agents are reprecipitated, the protein is found to be soluble, and the birefringence to have been largely restored. We may cite the following figures:

	Δ in % of control	Δ in % of control after reprecipitation and re-solution
$0{\cdot}5M$ LiCl	100	100
$0{\cdot}03M$ adenylpyrophosphate	50	74
$0{\cdot}1M$ $MgCl_2$	39	70
$0{\cdot}1M$ urea	30	100
$1{\cdot}0M$ urea	17	74
$2{\cdot}0M$ urea	10	65

After $6{\cdot}0M$ urea, however, neither solubility nor flow-birefringence are regained. There are, moreover, the restorations of flow-birefringence by treatment at 37°C., described in the previous paper, but further experience (which will be described elsewhere) leads us to think that they are rather different from the adenylpyrophosphate effect at or below 20°C.

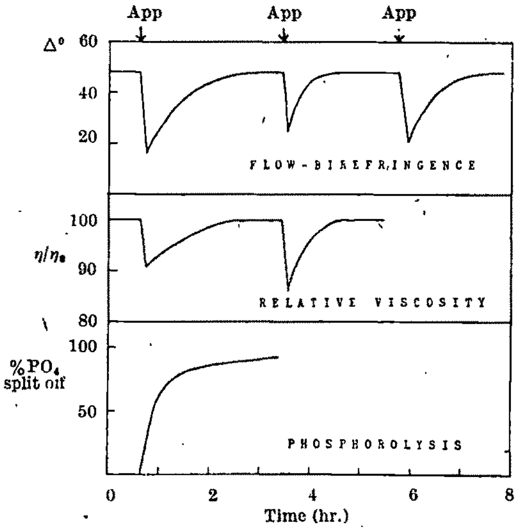

Fig. 2.

How do the effects described above compare with that produced by adenylpyrophosphate (prepared mostly by the classical method, but sometimes by that of Kerr and Seraidarian[7], which gives a purer product, freed from iron) upon myosin? When a myosin sol is treated with adenylpyrophosphate at concentrations as low as $0{\cdot}004M$, the flow-birefringence (Δ) is reduced by some 40–60 per cent, the anomaly is unaffected, and the relative viscosity (η) is reduced by some 20 per cent. The subsequent return of both Δ and η to their original values, which may take from a quarter of an hour to several hours, according to the conditions, is accompanied by the splitting off of inorganic phosphate from the adenylpyrophosphate. The fall of Δ and η is quite repeatable on the same sample of myosin—Fig. 2 shows an experiment in which three successive falls and returns of Δ were observed, two successive falls and returns of η, and over the first period the splitting off of inorganic phosphate was exactly measured. The question immediately arises whether we have to deal here with a true contractility of the myosin particles. Since the anomaly is retained, the particles must continue to be rod-like, but since the flow-birefringence is reduced, their axial ratio must be less than before. The decrease in relative viscosity would then be expected, as we know from work on polymers (see, for example, Kraemer and van Natta[8]; Powell and Eyring[9]) that η is proportional to polymer length at equal molar concentrations. But at the same time, in the absence of some sort of determination of the number of particles present, changes of aggregation and of hydration are also possible. But even were the phenomenon wholly one of disaggregation rather than true contraction, the physiological significance of the effect might be none the less.

As regards stoichiometric relations, varying the concentration of adenylpyrophosphate at 20°C. and neutral *p*H, shows that for a sol of 0·86 per cent protein approximately the full effect is obtained at $0\cdot004\ M$, falling off very rapidly at lower concentrations, and being very little higher at amounts up to $0\cdot2M$. It should be emphasized that this concentration is much lower than that of any of the other classes of substances which affect myosin's flow-birefringence. To produce a 60 per cent fall of $\triangle$, $1\cdot5M$ urea is required, $1\cdot0M$ monovalent cation, and $0\cdot2M$ divalent cation; or a *p*H of 10. From the dosage data a tentative calculation can be attempted, adopting the figures of Astbury and Bell[10], including a molecular weight of 67,000 for myosin, that thirty molecules of adenylpyrophosphate are required for every molecule of myosin, or one for every nineteen amino acids in the myosin chain. Whether the fact that phenylalanine and methionine occur sixteen times in the repeat unit, and tyrosine eighteen times, may have any significance in this connexion remains to be determined. But the possibility immediately arises that adenylpyrophosphate, the actual energy-providing substrate of the contractile protein itself, may in fact be the agent of contraction, which it would bring about by its initial combination with the enzyme.

One might perhaps picture the molecular length of adenylpyrophosphate being shorter than the length between the groups on the myosin chain to which it becomes attached, so that a contraction must accompany combination. This would be in line with the general two-affinity theory of enzyme action, only in globular proteins configurational changes in the enzyme protein would not be so readily observable as in linear proteins.

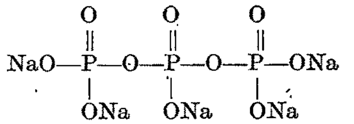
The evidence for the identity of myosin and adenylpyrophosphatase, resting upon the failure of all attempts to separate them, must remain of a negative character. But the fact that far-reaching optically observable changes in the myosin accompany the enzyme-substrate combination and the enzyme action, gives positive support to the view that the enzyme is myosin itself. It may therefore now be allowable to speak of a 'contractile enzyme'.

We should like to emphasize at this point that the viscosity data themselves suggested a specificity in the action of adenylpyrophosphate on myosin. With cations and at alkaline *p*H ranges $\triangle$ falls while η rises; with urea $\triangle$ falls while η remains constant; only with adenylpyrophosphate do $\triangle$ and η fall together to a limited and well-defined extent, which larger doses will not increase, and which is spontaneously reversed during the subsequent enzyme action. It therefore seemed important to explore more thoroughly the action of other substances which might have the same effect as adenylpyrophosphate. The following were tested at $0\cdot03M$ with quite negative results: lactate, glucose, glucose-1-phosphate (Cori ester), hexose-6-phosphate (Embden ester), hexose-diphosphate (Neuberg ester), glycerophosphate, phospho-glycerate, creatine-phosphate, adenylic acid, inosinic acid, aneurin, aneurin-pyrophosphate (co-carboxylase), diphenyl-pyrophosphate (Neuberg and Wagner[11]), inorganic pyrophosphate, metaphosphate, hexametaphosphate.

Any substances, of similar constitution to the substrate, and which combined with the enzyme, might be expected to show some degree of competitive inhibition. They would block the fall of $\triangle$ produced by adenylpyrophosphate, and inhibit the subsequent enzyme action.

The following substances were tested, and gave no such effects: inorganic orthophosphate, pyrophosphate, metaphosphate, hexametaphosphate, diphenylpyrophosphate, adenylic acid, inosinic acid.

We were able to observe the adenylpyrophosphate effect, however, using adenosine-diphosphate (prepared according to the method of Ljubimova and Pevsner[12]), but only on relatively unpurified myosin preparations. Thrice-precipitated myosin is not affected by adenosine-diphosphate, probably because the 'myokinase' of Kalckar[13], which converts it partly into adenylpyrophosphate, is removed by this purification. The adenylpyrophosphate effect is also fully given, even on thrice-precipitated myosin, by inosinic-(inosine-triphosphate)-pyrophosphate, where the amino group on the purine ring has given place to a keto-group (prepared by the method of Lohmann[14], and purified according to Kiessling[15]). An interesting result is obtained with inorganic triphosphate (prepared according to the method of Huber[16]):



$$\begin{array}{ccccccccc} & \mathrm{O} & & & \mathrm{O} & & & \mathrm{O} & \\ & \| & & & \| & & & \| & \\ \mathrm{NaO}- & \mathrm{P} & - & \mathrm{O}- & \mathrm{P} & -\mathrm{O}- & & \mathrm{P} & -\mathrm{ONa} \\ & | & & & | & & & | & \\ & \mathrm{ONa} & & & \mathrm{ONa} & & & \mathrm{ONa} & \end{array}$$

which, as Neuberg and Fischer[17] showed, is hydrolysed by muscle extract. This substance is split by the enzyme, giving inorganic phosphate, and as in the case of adenylpyrophosphate and inosine-pyrophosphate the process is accelerated by $Ca^{\cdot\cdot}$, but it has no effect whatever on the flow-birefringence. Correspondingly, it does exert a certain degree of competitive inhibition on the adenylpyrophosphate reaction, diminishing (in a typical experiment) the birefringence-reduction to 63 per cent of the control, and the phosphorolysis to 46 per cent of the control.

It would appear, therefore, to be highly probable that myosin is a specific triphosphatase. Since triphosphate combines with the protein and is split without causing any fall of $\triangle$, we may say with some plausibility that the purine-ribose end of the adenylpyrophosphate molecule is also of great importance in changing the shape of the protein molecule.

The only other attempt which has been made to elucidate the relationships of adenylpyrophosphate and myosin, which to-day seem crucial for any fundamental understanding of protein contractility, is that of Engelhardt, Ljubimova and Meitina[18]. Partially dried fibres of myosin, prepared by injection from extruders into distilled water, and still retaining some adenylpyrophosphatase activity, were treated with a variety of substances, of which alone adenylpyrophosphate showed any effect—an increase of extensibility. The concentration of adenylpyrophosphate used was similar to that found by us to be minimal for complete effectivity, that is, $0\cdot0025M$.
]

It is, of course, impossible to compare readily the results of two techniques so different, especially as the full details of the Russian work are not yet available.

In conclusion, it seems now fair to say that the interaction between adenylpyrophosphatase and its natural substrate brings about deep-seated and optically observable effects upon the enzyme's physical state. Whether these changes are micellar in character, or whether they are analogous to the configurational changes established for the keratins, remains as yet uncertain. Could adenylpyrophosphate itself then be normally *in vivo* the agent of contraction? Were this so, the reception of the nervous or other stimulus would essentially allow the enzyme and substrate to come in contact. By this enzyme-substrate combination the configuration of the contractile enzyme would itself immediately be changed (as pictured by Astbury and Dickinson[19]; Astbury[20]), and the later splitting off of inorganic phosphate from the substrate would supply the energy needed for the relaxation and recharging of the myosin fibril. The solution of these problems will be of much importance, not only for muscle physiology, but also for many other fields of biology into which fibre-properties enter, such as morphology and morphogenesis (cf. the recent work of Pollister[21] and Hobson[22]).

ACKNOWLEDGMENTS

We are much indebted to Dr. K. Bailey for the gift of a sample of diphenyl-pyrophosphate, and to Messrs. Kemball, Bishop and Co. for the gift of a supply of lithium chloride.

The work would scarcely have been possible without a grant-in-aid from the Rockefeller Foundation, which supports two of us (A. K. and M. M.), and for which we are deeply grateful.

OBITUARIES

Prof. A. R. Forsyth, F.R.S.

PROF. ANDREW RUSSELL FORSYTH, emeritus professor of the Imperial College of Science and Technology, South Kensington, died on June 2 at Bailey's Hotel, London, where he had lived since he retired in 1923 from his position as chief professor of mathematics at the Imperial College. His age just fell short of eighty-four, as he was born (at Glasgow) on June 18, 1858.

He was educated at Liverpool College and at Trinity College, Cambridge. His student career at Cambridge was brilliant: he was Senior Wrangler, and First Smith's Prizeman in 1881, in which year also he was elected to a prize fellowship at Trinity. In the following year he became professor of mathematics at University College, Liverpool, but two years later, in 1884, he returned to Cambridge as a lecturer of his college and of the University. In 1895 he became Sadleirian professor of pure mathematics at Cambridge in succession to Cayley, whose voluminous collected papers he edited (1895–98).

While still in his twenties Forsyth attained a reputation as a pure mathematician that extended far beyond the borders of his own university and country. His distinguished researches, an account of which is given separately below, led to his election as a fellow of the Royal Society at the early age of twenty-seven, and eleven years later he was awarded a Royal Medal of the Society. In the same year he was president of Section A of the British Association at its Toronto meeting, a distinction which he held a second time in South Africa in 1905. He was president of the London Mathematical Society during 1904–6.

Besides making important original contributions to pure mathematics, Forsyth rendered a service of special value to his university in breaking the bonds of the isolation of its mathematical school, during the latter part of the nineteenth century, from the great Continental movements of thought in the subject. By his writings and his lectures he widened the knowledge and outlook of his colleagues and students, and stimulated a revival of pure mathematical learning and research in England.

Forsyth was a prolific author of books, beginning in 1885 with a text-book on differential equations, that has run through many editions, and has been translated into several languages; this was followed by a large treatise on the theory of differential equations, in several volumes (1890–1906), and by an attractive text-book on the theory of functions (first edition in 1893).

During his Cambridge period he found time also to take part in the government of the University, as a member of the Senate during 1890–1910; and in other public work, for example, as a member of the Treasury Committee on the Scottish Universities, in 1909.

For many years Forsyth was regarded abroad as the leader and representative of English pure mathematics, and honours from universities and academies the world over were bestowed upon him. He maintained many personal and official international contacts; he travelled much and was an accomplished linguist.

In the midst of his fame he left Cambridge (1910), resigning his chair and the college fellowship that meant so much to him. In painful circumstances he made a marriage of affection, and gained ten years of a happiness for which he counted the loss of many old associations a price not too high. For a time he was without any official position, and during this period he delivered in Calcutta (1913) a series of lectures on differential geometry (afterwards published as a book).

Forsyth entered on the last phase of his teaching career when in 1913 he accepted the headship of the department of mathematics at the Imperial College, combining the direction of two previously separate schools (one in the Royal College of Science, the other in the City and Guilds Engineering College) headed by Profs. Perry and Henrici, who retired nearly at the same time. The War of 1914–18, and its aftermath, interrupted his plans for building up a new honours school of mathematics at South Kensington, and he retired from his chair in 1923, after ten years tenure, on attaining the age limit of sixty-five.

His wife had died of cancer not long before, to his intense grief; he cherished her memory most tenderly, and in his will he left his residuary estate to the Royal Society for cancer research.

In his lonely retirement Forsyth found solace in his mathematical studies, and published two further treatises, on the calculus of variations (1927) and the geometry of four dimensions (1930); he also continued his linguistic studies.

His last years were clouded by frequent illness. His thoughts dwelt much on his Cambridge days, particularly on the old-time Tripos conditions of his student period, and on the Senior Wranglers of those years. In his last illness his mind lived in this golden epoch of his youth. S. CHAPMAN.

THE old Tripos admitted of very little specialization, and a Senior Wrangler was bound to have a competent knowledge of every branch of mathematical science known to the Cambridge of his day. The emphasis was generally on mathematical physics, in which England led the world; and Forsyth's first original paper—written when he was still an undergraduate—was on the motion of a viscous incompressible fluid. Immediately after taking his degree, he began to work on a fellowship dissertation; for some time he toyed with the kinetic theory of gases, but finding this unprofitable, he turned to an idea which had occurred to him when listening to Glaisher's advanced course on elliptic functions, and in two months produced the great memoir on the double theta functions, which occupies 79 pages of the *Phil. Trans.*, **173**, and which, besides winning the fellowship, laid the foundation of his fame as an original investigator.

The subject was well suited for the display of Forsyth's most characteristic gifts: a masterly algebraical technique in dealing with vast numbers of symbols, and a wonderful power of detecting identities and relations in problems of great complexity. In the following year he wrote a long and valuable paper on a closely related subject, Abel's theorem and Abelian functions, which was printed in *Phil. Trans.*, **174**, and after this a substantial work on the Weierstrassian doubly periodic functions (*Quart. J. Math. Soc.*, **22**), which he introduced to Cambridge mathematicians (Glaisher always adhered to the Jacobian *sn, cn, dn*). It is somewhat remarkable that although a pupil and fervent admirer of Cayley, he had up to this time done nothing on Cayley's great subject, the invariant-theory of algebraic forms; and when he did come to it, in 1887, it was not directly but by the roundabout way of differential equations. In a single year, 1889, he published five papers, totalling 284 pages, on the concomitants of algebraic and differential forms; and in the next year, more than a hundred pages in the *American Journal of Mathematics* on a topic in the same field, "Systems of ternariants that are algebraically complete".

The following years were spent chiefly in preparing himself for writing a book which had perhaps a greater influence on English mathematics than any work since Newton's "Principia", namely, the "Theory of Functions of a Complex Variable", which was published in 1893. This for the first time opened to his countrymen the vast development of pure mathematics which had taken place on the Continent in the nineteenth century; it broke the Cayley tradition, and led all the younger generation at Cambridge into the new domain. On Forsyth's part it was a patriotic and self-sacrificing action; for while the fresh impetus brought vigour and fame to the school, the situation was not well suited for the exercise of his special aptitudes: there was little opportunity of superb generalship with symbols, and his somewhat unphilosophical mind was at a disadvantage when confronted with the new type of problems. Moreover, by turning everyone's attention away from the subjects in which his greatest triumphs had been won, he caused what was in effect a lowering of his own popular reputation.

Another factor which perhaps likewise tended in some degree to displace Forsyth from the supreme position which he held in the general estimation at the end of the nineteenth century was the practice, which he adopted from this time onwards, of publishing most of his discoveries, not as they were made, in separate papers, but in advanced treatises (some of them of colossal size), each summing up the work of several years. Human nature being what it is, a worker on the remotest frontier of pure mathematics would probably be well advised to impart his results to the world by instalments smaller than those customary with Forsyth; few people are willing to tackle what is practically a continuous heavily analytical original memoir of eight hundred pages. But whatever may be thought of the practical wisdom of his later policy, the great memoirs of his earlier period will secure for him permanently one of the high places in the mathematical pantheon.

E. T. WHITTAKER.

Mr. W. A. Benton

WE regret to record the sudden death of William Alfred Benton at his home at Handsworth, Birmingham, on June 19, at the age of seventy-one. For many years Mr. Benton was in charge of research at Messrs. W. and T. Avery Ltd., Soho Foundry, Birmingham, and was a well-known figure in scientific circles. He was a fellow of the Physical Society and a past president of the Birmingham Metallurgical Society; among other activities he was a member of the Society of Chemical Industry, the Newcomen Society and the Wolverhampton and District Society. During the past few years Mr. Benton had been compiling a work on the history of the balance, and it is fortunate that the greater part has already been completed.

Outside his professional interests, Mr. Benton was a keen amateur photographer, and was a member of the Royal Photographic Society and local photographic societies.

WE regret to announce the following deaths:

Mrs. F. Rhys Davids, president and co-founder of the Pali Text Society, on June 26, aged eighty-four.

Lord Glanely, president of the University College of South Wales and Monmouthshire, at Cardiff, on June 28, aged seventy-four.

Sir Daniel Hall, K.C.B., F.R.S., formerly director of the John Innes Horticultural Institution, and for some years chief scientific adviser to the Ministry of Agriculture, on July 5, aged seventy-eight.

NEWS and VIEWS

Colonial Research Committee

THE Right Hon. Viscount Cranborne, Secretary of State for the Colonies, was present at the inaugural meeting of the Colonial Research Committee held on June 29, and defined the scope and purpose of the Committee's work (see NATURE, July 4, p. 17). He said that the Committee will have two functions. In the first place it is to advise the Secretary for the Colonies on schemes for assistance from the £500,000 a year which is provided under the Colonial Development and Welfare Act for "research and inquiry". But this is only part of a wider function; what is needed is a broad survey of the whole range of research in Colonial studies. We need to know, first, what subjects ought to be studied, secondly, what is being done now, and thirdly, what can and should be done to fill the gaps. In several respects the field is not at present adequately covered. The older sciences have in this respect the advantage; but there are newer sciences, the application of which to Colonial questions has not at present gone very far. Many of these could render work of immediate practical value to the Colonial Empire.

Lord Cranborne then emphasized that the Committee should undertake "inquiries". There will undoubtedly be many applications, he said, from Colonial Governments for assistance in making inquiries that will be of immediate practical value to them—jobbing inquiries that the pure scientist may rather scorn to describe as research proper. The Government's intention, however, is that the Committee should include all forms of inquiry in its field—the ascertainment, collection and assessment of all facts that may be of value to the Colonial Empire. This is not to be interpreted, however, as limiting investigations to research of immediate application to Colonial problems. In attempting to define "Colonial studies", Lord Cranborne pointed out that while there is little that is common to all parts of the Colonial Empire, there are some things that are common to large parts of it. For example, most of the Colonies are in the tropics, they are engaged in primary production, in agriculture rather than in industry. Most of them are maritime, and many parts of them are inhabited by peoples who have only recently come into contact with Western civilization. Hence questions relating to tropical health, agriculture and engineering, fisheries and all questions relating to the development of peoples in contact with more advanced civilizations are of interest to the Colonial Empire and thus to the new Committee. Finally, there are large groupings of the Colonies geographically. There are, for example, many Colonies in Africa; all scientific questions relating to Africa, and particularly to tropical Africa, would therefore come within its range of activities.

The Committee, said Lord Cranborne, will inevitably have contacts with many others, outside the Colonial Empire itself, working on problems which are yet of interest to the Colonies. Apart from institutions in Great Britain, there are many in India and the Dominions, particularly perhaps South Africa, and many too in various foreign countries. The other Colonial Powers, for example, all have research institutions, which in happier days after the War will exist again. We share many problems and can share too in their solution—the control of locusts, tse-tse fly research, nutrition and so on. With the United States too we have already a long and happy tradition of collaboration on research matters. Scientific problems do not recognize national boundaries; they will assuredly provide, in the future as in the past, a fruitful field of international co-operation. Lord Cranborne also expressed the hope that the Committee will make it one of its objects to develop research work actually in the Colonial Empire itself. There has been in the last twenty years or so a rapid development of the educational institutions in the Colonies. The addition to such institutions of research workers, engaged primarily in the pursuit of pure knowledge without too close a concern with its practical application, is of great value in fostering an atmosphere of true learning.

Nutritive Value of Meals in 'British Restaurants'

THE feeding of the people of Great Britain during the War is based on scientific knowledge, a great proportion of which has been gained during the last twenty-five years. In the War of 1914–18 sufficient was known about calories, protein and perhaps vitamin C to ensure that these factors were taken into consideration in the choice of food supplies. Disaster, however, might well have overtaken us through ignorance then of requirements of vitamin A. Those who advise the Ministry of Food to-day must therefore use what information they can acquire to ensure, in this War, that no deficiencies of, say, pantothenic acid, vitamin B_6 or biotin affect the national health.

Meals served in British Restaurants represent in many cases a substantial part of the diet of those eating them, and an investigation of the nutritive value of the food actually served on the plates is calculated to give information of great importance. To get such information the Ministry has enlisted the co-operation of a number of scientific workers in universities, hospital laboratories and elsewhere. Each of these workers has taken the responsibility of overseeing each month the type of meal served in his area. In addition, each will analyse the meals for vitamin C at least and, where laboratories have the facilities, investigations of less well-known vitamin factors, analyses of protein or the experimental determination of calorific values will also be undertaken. As the War continues and food supplies become more restricted, it is against unexpected deficiencies that we must guard. Thus the workers who are voluntarily giving their skill and knowledge to the Ministry of Food will be making a real contribution to the national effort.

Medal Awards of the Royal Society of Arts

THE Albert Medal of the Royal Society of Arts for 1942 has been awarded to General J. C. Smuts, Prime Minister and Minister of External Affairs of the Union of South Africa. In deference to General Smuts's well-known preference for brevity and simplicity the following words will be inscribed on the medal: "Statesman. Soldier. Scientist. Philosopher".

Silver medals have been awarded for the following papers read before the Society during the past session: *Papers read at Ordinary Meetings*:—Mr. J. C. Dawes, "Making Use of Waste Products"; Prof. H. D. Kay, "The Future of the Milk Industry"; Mr. James Kewley, "Evolution in the Petroleum Industry"; Mr. E. M. Rich, "Technical Education". *Papers read before the India and Burma Section*:—Sir Bernard Darley, "The Development of Irrigation in India"; Mr. A. J. Gibson, "The Story of Lac"; Dewan Bahadur S. E. Runganadhan, "The Work of Indian Universities". *Paper read before the Dominions and Colonies Section:* Dr. Maurice Ashby, "British Empire Drug Production". *Endowed Lecture:* The Right Hon. Viscount Bennett, "Empire Relations".

American Chemical Society Prize in Pure Chemistry

THE American Chemical Society Prize in pure chemistry of 1,000 dollars has been awarded for 1942 to Dr. John Lawrence Oncley, associate in physical chemistry at the Harvard Medical School and instructor in chemistry at the Massachusetts Institute of Technology. This Prize is given annually for "outstanding research in pure chemistry by a man or woman less than thirty-six years old". Dr. Oncley has made important contributions to protein chemistry, and he has investigated the dielectric properties of gases, insulating oils, resins, rubbers and proteins, developing radio-frequency bridge methods suitable for precise dielectric constant determinations with proteins. With the aid of these methods he completed the first satisfactory study of the dielectric dispersion behaviour of water-soluble proteins. This work constitutes one of the significant contributions of recent years to protein chemistry and has led to further studies on the molecular size and shape of protein molecules.

Award of the Dr. W. S. Bruce Memorial Prize

THE joint committee consisting of representatives from the Royal Society of Edinburgh, the Royal Physical Society and the Royal Scottish Geographical Society has awarded the Bruce Prize to Dr. G. C. L. Bertram for valuable biological work in the Arctic and Antarctic during 1932–37; and especially for his work as biologist with the Graham Land Expedition during 1934–37, when he took part in the important sledging journey which discovered King George VI Sound. His particular work was on seals, and he has written an important memoir entitled "The Biology of the Weddell and Crabeater Seals", published by the British Museum (Natural History) in September 1940 in the British Graham Land Expedition Reports. In addition, Dr. Bertram is the author of a more popular book on the technique of polar travel entitled "Arctic and Antarctic".

Bicentenary of Abraham Sharp

ON July 15, 1742, the mathematician and astronomer Abraham Sharp died at his birth-place, Little Horton, near Bradford, Yorks., at the age of ninety-one, having in various ways furthered the interests of British astronomy. After serving an apprenticeship to a merchant at Manchester, he opened a school at Liverpool, where Flamsteed met him. The meeting led to Sharp joining Flamsteed in the newly erected Royal Observatory at Greenwich where he worked from 1676 until 1690. In 1688 Sharp was given the task of constructing a mural quadrant of 79 in. radius, and this proved to be the most satisfactory instrument Flamsteed possessed. With his other instruments it was removed from Greenwich by his executors after Flamsteed's death, but some eighty years ago parts of a similar instrument by Sharp were given to the Observatory by the Rev. N. S. Heineken. On leaving Greenwich, Sharp settled at Little Horton, calculating, making instruments and corresponding with scientific men. He supplied Flamsteed with observations, and with Crosthwait, Flamsteed's last assistant, he had a share in the publication of the "Historia Cœlestis Britannica", which appeared in 1725, six years after Flamsteed died. In a letter written in January 1722 Crosthwait wrote to his collaborator that "the memory of the ingenuous and disinterested Mr. Sharp will always, by me, be had in the greatest esteem, next to that of my deceased and good friend Mr Flamsteed".

Dr. Charles B. Dudley, 1842–1909

EACH year, the American Society for Testing Materials awards a medal for some outstanding contribution to research in engineering materials, and to commemorate the eminent services of the Society's first president, Dr. Charles B. Dudley, who was born on July 14, 1842. Brought up in Chenango County New York, Dudley at the age of twenty enlisted in the 114th New York Volunteers, fought in a number of battles during the Civil War, and was severely wounded. In 1865 he was free to resume his interrupted studies, and during the next nine years worked at the Oxford Academy, Chenango Co., Yale College and the Sheffield Scientific School of Yale College. Part of his time was spent on newspaper work to provide him with necessary funds. On leaving Yale in 1874 with the degree of Ph.D., he devoted a short time to teaching chemistry and physics at the University of Pennsylvania and at a Military Academy at Poughkeepsie; and then in 1875 became chemist to the Pennsylvania Railroad Company, with headquarters at Altoona, Pa., where he installed laboratories. Much of his work was of a pioneering character and it gradually spread to investigations on all the materials used in the building and working of a railway, from the laying of the track to the ventilation of carriages. Especially important were his researches on rails. Besides being the founder-president of the American Society for Testing Materials, he served as president of the American Chemical Society and at the Copenhagen Congress of the International Association for Testing Materials held in 1909 he was chosen president for the ensuing three years. Soon after his election, however, he died unexpectedly on December 21, at the age of sixty-seven.

30-kw. Short-Wave Radio Transmitter

AN article by F. D. Webster and R. E. Downing (*Elec. Comm.*, 20, No. 3, 1942) describes a new equipment built for All America Cables and Radio Inc. for use in the expansion of its international service at Lima, Peru. The equipment is capable of operating on any frequency between 5·7 mc. and 22 mc., with crystal control or with self-excitation, for carrier wave or modulated carrier wave telegraphy or by means of a separate modulator for telephone or broadcast, to deliver 1 kw. or 30 kw. of radio frequency power on telegraphy or 9 kw. on telephony or broadcast, and of delivering its rated output at any frequency between 5·7 mc. and 22 mc. into a balanced transmission line of 600 ohms surge impedance with any standing wave ratio up to 2 to 1.

Flexibility is achieved by constructing the equipment in four mechanically separate units and by the provision of controls which permit rapid and convenient transfer to any type of operation. The four units comprise a radio frequency driver, a power amplifier, a 3,000-volt rectifier and a 10,000-volt rectifier. For telephone operation two more units are required, namely, a speech amplifier and a modulator. Voltage breakdown, which is an ever-present hazard due to the high voltages produced in radio equipment of this power, is minimized by adequately spacing and insulating all components, by avoiding sharp edges on metal parts, and by installing corona shields and horn gaps where applicable. Excessive temperatures are avoided by employing adequate current-carrying capacity in all conductors, ample radiating surfaces, water cooling, and forced air circulation by means of blowers.

Recent developments incorporated in this equipment include electronic keying with weight control, modulated carrier wave telegraphy by phase modulation, special type balancing network, multistrand filament tube, vacuum condensers. The article gives, at some length, details of the electrical design and the mechanical construction of the general assembly of the equipment and of the component parts which come broadly under the headings of controls, personnel protection, radio frequency driver unit, power amplifier unit, 3,000-volt rectifier unit and 10,000-volt rectifier unit. A table of specifications summarizes the more detailed equipment description.

Optics Applied to Engineering

A LECTURE entitled "Optics Applied to Engineering" was delivered by Mr. K. J. Habell at a meeting of the Leicester Branch of the Association of Scientific Workers held on June 2 at the College of Technology, Leicester. Mr. Habell described the principles of several types of optical instruments now in increasing use in engineering workshops, and much interest was shown in those of the more difficult types of profile projection. The application of telecentric systems for the avoidance of magnification errors due to incorrect focusing and to ensure the imagery of the correct profile was very well illustrated by diagrammatic and experimental slides showing the images of a circular hole produced by convergent, divergent and collimated beams of light. Other instruments described included the tool-room microscope for the examination of form tools and screw-thread forms, and alignment telescopes for measuring the alignment and relative tilt of closely or widely separated bearings and jigs. Details were given of auto-collimating telescopes for high precision work in angular measurement. The importance to the war effort of instruments of the types described was emphasized. A selection of the instruments was on view, and was demonstrated after the meeting.

Chemical Engineering at Leeds

THE Department of Coal Gas and Fuel Industries (with Metallurgy) of the University of Leeds was established in 1906 to provide degree courses in fuel and metallurgy. In 1910 a fund was raised by the gas industry in order to perpetuate the memory of Sir George Livesey, the distinguished gas engineer, and this was allocated to endow the chair of the Department now known as the Livesey professorship. A degree course in gas engineering was instituted at that time. Since then the Livesey Advisory Committee, which is composed of representatives of the Institution of Gas Engineers, of the Society of British Gas Industries, and of the University, has had under consideration the need for extending the courses in order to keep pace with the growth of knowledge and the increasing demands of industry. In particular, for those passing into the constructional side of the gas industry and into the larger undertakings as well as to the staffs of chemical plant manufacturers generally, a broader training is necessary. On this account the Committee recently recommended the establishment of an alternative four-year course in chemical engineering, which has now been approved by the University; the new course will begin with the autumn term.

Domestic Electricity Supply

AN optional-control system of domestic electricity supply is described by P. Schiller (*J. Inst. Elec. Eng.*, 89, Pt. 2, No. 9; June, 1942), which is designed to meet the objection often raised to domestic load control of any kind, in that it involves encroachment on the consumer's liberty to use his supply as he wishes. It is suggested in the paper that the consumer be given the opportunity at any moment and for any period of time readily to change over from a controlled to an uncontrolled supply, and vice versa, the consumption during periods in which the load control is made inoperative being charged at a higher price. The price change can be effected by a gear-change device in the kwh. register or in the prepayment mechanism of the meter, actuated in conjunction with the changeover in the operation of the load control. The necessary modification of apparatus and the extra cost entailed are both of a minor nature.

Siting of Power Stations

A PAPER by F. Favell (*J. Inst. Elec. Eng.*, 89, Pt. 2, No. 9; June 1942), on the considerations to be given to this subject, points out that in recent years the siting of electricity-generating stations has tended to be affected increasingly by non-technical considerations such as legal requirements, amenities, etc. These considerations become of special importance when a particular scheme is submitted to a public inquiry by the Electricity Commissioners under Section II of the Electricity (Supply) Act, 1919. The paper records some of the issues to be borne in mind when siting power stations in Great Britain and at the same time it refers to some factors which have a bearing on power station construction irrespective of location. It is divided into two main parts, the first dealing with considerations arising out of parliamentary legislation, and the second with more technical and practical problems. The first part refers to the Town and Country Planning Act, 1932; the Coal Act, 1938; the Coal Mines Act, 1930; and various other statutory requirements. The second part deals with chimney emissions; sewage effluent for circulating water; amenities; and alternative sites.

Californian Fisheries

THE report on the commercial fish catches of California for the year 1940 (State of California Department of Natural Resources. Division of Fish and Game. Bureau of Marine Fisheries. Fish Bulletin No. 58; 1942) makes available the summaries of commercial fish landings in each region of the State and also includes tables of numbers and nationality of the commercial fishermen and the number of boats of each type engaged in the fishery. A rapid development of the shark fishery is outstanding and is caused by the high price offered for liver oils of high vitamin A potency. This increase in the shark fishery, with intensive mackerel fishing and the large amount of sport fishing, has resulted in an increase of 350 boats in 1940–41 registrations over the previous year and is most noticeable in the group between 25 ft. and 39 ft. long. There has been a steady development of sport fishing in the ocean waters of Southern California, and the amount of small fish required as bait must be considered together with its effect on the several species used as bait. The statistical records include not only the sport catch itself but also the harvesting of the small-sized fishes used by the anglers for bait. Sardines and anchovies are the most important in the bait catch, comprising 98 per cent of the total, the fishes being 2½–6 in. long. A useful list of the common and scientific names of fishes, crustaceans and molluscs involved in the fisheries is given at the end of the report.

Inter-American Friendship through the Schools

THE U.S. Office of Education has issued as Bulletin No. 10, 1941, "Inter-American Friendship through the Schools", a report based upon a research study conducted by the Office of Education for the specific purpose of ascertaining the extent of inter-American studies, that are already a part of the school curriculum. The bulletin is based largely on the replies of school administrators to a questionnaire, and the central purpose of the investigation was to discover the opportunities of learning which the curriculum presents and the patterns of teaching relative to the development of inter-American understanding that are to be found in the elementary and secondary schools of the United States. From the 6,623 administrators to whom the questionnaire was sent, 2,471 replies were received in time to be tabulated for the report. Of these, 671 stated that Spanish was being taught, and one half of the schools reporting indicated that, although they did not offer Spanish, they provided a study of the other Americas in various courses given in English. No study relating to the other American republics in Spanish or in English was reported by 521 of the schools.

Dinosaur Find at Washington, D.C.

IT is stated by Science Service, of Washington, D.C., that the broken upper part of a saurian thighbone has been found in a new excavation being made for the D.C. filtration plant at Washington. The bone was identified as belonging to one of the sauropod group of dinosaurs by Dr. C. W. Gilmore, curator of vertebrate palæontology at the U.S. National Museum. Two finds of dinosaur bones have previously been made in Washington; they were of rather fragmentary fossils. Judging from the size of the present find, Dr. Gilmore said, the original animal was about ten feet high at the hips and fifty or sixty feet long, weighing approximately ten tons. Apparently, from the geological evidence, it was trapped in a small pond or mudhole and so perished. These creatures lived during the Cretaceous, about 150 million years ago.

Restoration of Historic Monuments in the U.S.S.R.

A SPECIAL committee for the registration and protection of architectural relics and historic monuments has been set up by the Soviet Government. It consists of leading members of the Academy of Sciences and architects, headed by Igor Grabar, a Stalin prizewinner. One duty of this committee will be to establish the amount and nature of the destruction and damage caused by the Germans in occupied districts and, where restoration is at all possible, to supervise the work.

Cosmic Ray Research

AN expedition of the Academy of Sciences of the U.S.S.R., led by Prof. A. I. Alikhanov, has arrived in Erevan, the capital of Soviet Armenia, to study cosmic rays. It will be in the field for about six weeks, making observations at the high-altitude meteorological station in the Alpaz mountains.

Recent Earthquakes

A SEVERE earthquake shook the towns of Santiago and Valparaiso and the region between the towns at about 1.30 a.m. (local time) on June 29. The *Intendencia*, headquarters of the Provincial Government, and other buildings were damaged in Valparaiso. Property was also damaged in Santiago, and for a while the electricity supply was interrupted. Thirty-seven people were reported injured. The earthquake was probably the most severe in Chile since 1927, when Talca and Concepcion were destroyed.

A moderate earthquake shook the town of Karachi at 8.30 a.m. approximately on the morning of July 3. No damage has been reported.

Free German Institute in London

A FREE German Institute is being founded by the science section of the Free German League of Culture in Great Britain. The aims of the Institute are: (i) to uphold and develop the valuable traditions of the Free German research work and teaching; (ii) to provide for interchange of opinion between Free German men of science and those of the United Nations; (iii) to strengthen the German refugee youth in the spirit of international understanding, and to enable them to help in re-shaping Germany's cultural life after the destruction of Nazism. The opening session will be held on July 17 at 7.30 p.m. at the Everyman Theatre, when an address will be given by Dr. Joseph Needham. Further particulars of the movement can be obtained from the secretary, Free German League of Culture, 36 Upper Park Road, London, N.W.3.

Announcements

THE honorary degree of D.Litt of the University of Oxford has been conferred on Commander Claude Schaeffer, of the Free French Navy, who is deputy curator of the Musée des Antiquités Nationales at Saint-Germain, and conducted important archæological excavations at Ras Shamra in North Syria.

A WHOLE-DAY conference is being arranged by the Nutrition Society, jointly with the Food Group of the Society of Chemical Industry, on "Dehydration of Foods and the Effect on their Nutritional Value", to be held at the British Medical Association House, London, on July 25. A later meeting, probably at the end of October, will deal with "Trace Elements in Nutrition". Further particulars of meetings can be had from the honorary secretary of the Nutrition Society, Dr. Leslie Harris, Nutritional Laboratory, Milton Road, Cambridge.

Raman's Theory of Specific Heat of Crystals

A DESCRIPTIVE article by Dr. W. H. George surveying some recent papers by Sir C. V. Raman and his school[1,2] having appeared in NATURE of May 16, we wish to make a few comments. A detailed criticism of Raman's paper will appear elsewhere.

(1) Raman rejects the result of lattice theory that the vibrational spectrum of a crystal consists of several (three or more) practically continuous branches, and contends instead that it consists of a few discrete vibrations. He bases this assumption on the observation that only a few sharp lines appear in optical absorption and scattering.

Lattice dynamics explains this fact by the optical selection rules: only those mechanical vibrations react with light waves which are in phase in a region of the order of a wave-length. As the wave-lengths concerned are long compared with the lattice constant, this selection rule restricts optical resonance to a practically monochromatic region in each branch of the spectrum. Hence the optical facts provide no argument against lattice dynamics.

(2) Raman[1] calculates the specific heat by superposing a few Einstein functions according to his interpretation of the spectrum. But in the majority of cases treated by his collaborators (Norris, Dayal, Anand, Venkateswaran[2]), these vibrations are not taken from optical data but chosen in such a way as to obtain a fair agreement for the specific heat. These calculations prove therefore only the well-known fact that a few Einstein functions can be fitted to the specific heat data of a solid. Nernst and Lindemann[3] showed in 1911 that even two frequencies in the fixed ratio 1 : 2 were quite sufficient for many substances. Born[4] has shown further that the higher branches of the vibrational spectrum cover a small frequency interval and can be replaced, for calculations on the specific heat, by a monochromatic vibration. But this is an approximation, and the fundamental fact that a system of $N \simeq 10^{23}$ particles has $3N$ modes of vibration cannot be explained away.

In the case of rock salt an attempt is made (Venkateswaran[2]) to relate some of the vibrations to peaks in the Raman spectrum; but strangely enough these were considered to be octaves of the required lattice vibrations. The frequencies of sylvine are all taken to be 0·78 of those of rock salt. All these assumptions are quite arbitrary and do not lead to results better than those given by previous calculations (see accompanying table).

(3) Raman's rejection of Debye's theory is based mainly on the alleged better agreement of Raman's formulæ with observation. But Debye's formula contains only one frequency and that not arbitrary, but expressible in terms of the elastic constants. It is very likely the best one-constant theory possible and serves remarkably well for monatomic substances. Its deficiencies appear at very low temperatures where particular phenomena are observed (for example, an increase in the value of the Debye parameter for NaCl with falling temperature). These have been satisfactorily explained by the rigorous lattice dynamics[5,6].

As an example, the experimental specific heat values found for rock salt by Clusius and Perlick[7] are tabulated below, together with the values calculated by Kellermann[6]; the last column is taken from a table calculated by Venkateswaran[2] applying Raman's theory.

$T°$ K.	C_v (expt.)	C_v (lat. theory)	C_v (Raman's theory)
10	0·0326	0·0328	0·036
20	0·310	0·317	0·28
30	1·150	1·154	0·96
40	2·380	2·380	2·04

(4) Raman rejects lattice dynamics because it uses the postulate of the 'cyclic lattice' for the calculation of the vibrations. Raman considers this an arbitrary assumption which leads to wrong results. In fact it is a reasonable method of approximation against which no mathematician has ever raised a doubt. The rigorous solution was known for the monatomic linear lattice, where it leads to the same results; in order to refute Raman's objections the correct solution for a di-atomic linear lattice has been worked out[8], and again complete agreement with the cyclic method was found. It must further be remembered that most of the well-confirmed results of the quantum theory of electrons in metals (electric conductivity, metal optics, etc.) are based on the cyclic method and can be considered as confirmations of it.

(5) Raman considers the frequencies of a lattice to a first approximation as those of the inner vibration of the single cell; but he suggests that there is an influence of the neighbouring cells which can be taken into account. This is in fact a reasonable and well-known way[4] of approximating to the higher (optical) branches; but it fails completely for the lower (acoustical) branches, and is therefore useless for monatomic lattices (all metals) where there are no higher branches, and, more generally, for substances (like the alkali halides) where it is not possible to consider the atoms in a cell as bound together with stronger forces than those connecting them to the neighbouring cells. It is in these cases that good confirmation is obtained for lattice dynamics in calculating the lattice energy, and elastic, optical, piezo-electric and other constants. All this would have to be abandoned if Raman's ideas were correct.

(6) Raman's theory has been devised to justify his interpretation of the diffuse X-ray scattering. It has been shown[9] that this interpretation is in contradiction with observations and with well-established theory, and that lattice dynamics accounts for the facts more satisfactorily. The diffuse X-ray spots are nothing but photographic images of the quasi-continuous spectrum derived from the lattice theory which Raman attacks.

Absorption Spectra of 3-4 Benzpyrene

Evidence has been given[1] that benzpyrene emits various fluorescence spectra according to its physical state. Molecular benzpyrene, the monoclinic, the orthorhombic crystallized modification and the colloidal suspension in water fluoresce violet, green, blue and yellow respectively. The fluorescence spectrum of dissolved benzpyrene is unchanged in various solvents except for slight displacements of the entire group of bands[2]. We have now studied the absorption spectra with a low-voltage projection lamp as a light source for a continuous spectrum, which restricted the observation to the radiation transmitted by glass. It was found that the first broad absorption band of dissolved benzpyrene[3] has three components, α, β, γ, at 383, 380 and 377 mμ respectively in hexane (Fig. 1,*a*). They are of almost the same strength, but they behave differently in various solvents. While the α-component persists as the maximum, β and γ fuse and disappear more or less by polar effects due to the solvent.

The absorption spectrum of the blue fluorescing orthorhombic modification of solid benzpyrene (Fig. 1,*b*) is entirely different from that of the dissolved hydrocarbon. It shows a broad absorption band between 415 and 425 mμ which is accompanied by three narrower bands at 405–410, 392–396 and 384–387 mμ respectively. In order to delay the spontaneous transformation[1] of the metastable orthorhombic into the stable monoclinic crystals, very thin crystal films were prepared by evaporating a benzene solution of benzpyrene on cover glasses. A pile of six such films absorbs strongly enough to render visible the long wave-length portion of the absorption spectrum.

The monoclinic needles which fluoresce green, and their colloidal yellow fluorescent suspension in water, cannot easily be prepared in a state which is suitable for absorption spectroscopy. An indirect method was devised which allowed this difficulty to be overcome. It is based on the observation of Bowen and Sawtell[4] that the fluorescence efficiency of a fluorescent solution is usually independent of the wave-length of the exciting radiation within wide limits. Hence, if a continuous spectrum is focused on to the fluorescent substance in a layer so thin that the absorption is *feeble*, the absorption spectrum appears as fluorescent light. This can be recorded by a photographic plate if a thin film filter is placed between the fluorescent layer and the photographic emulsion, which completely absorbs the exciting short wave-length radiation and transmits the fluorescent light. Henri and Wurmser[5], by this technique, separated from a discontinuous spectrum the radiations which excite the fluorescence. Fig. 2 shows positives of 'fluorograms' of molecularly dissolved benzpyrene in Canada balsam (*a*), of the orthorhombic form as a single layer of sparsely distributed thin crystal squares of about 5 μ side under water (*b*), of the monoclinic form as a loose mosaic of microscopical crystal leaves on a cover glass (*c*) and of a colloidal suspension of benzpyrene in water (*d*). The fluorograms *a* and *b* repeat as luminous bands the dark bands of Fig. 1,*a* and 1,*b* although in a different strength. The same flat maxima of Fig. 2,*c* and 2,*d* at about 425 mμ establish the fact that the particles of the colloidal suspension are ultra-microscopical monoclinic crystals.

(*b*) Pile of 6 orthorhombic crystal films. Increasing exposures.

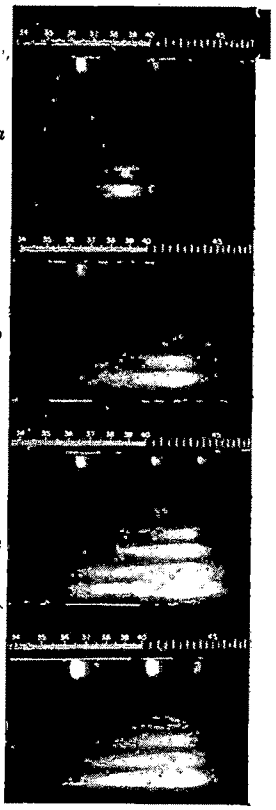

Fig. 2.
FLUOROGRAMS (POSITIVES) OF BENZPYRENE. INCREASING EXPOSURES.
(*a*) Dissolved in Canada balsam.
(*b*) Orthorhombic crystals in water.
(*c*) Mosaic of monoclinic crystals on glass.
(*d*) Colloidal suspension in water.

The method permits of recording—at the present stage, qualitatively—the absorption spectra of systems which are not suitable for the usual spectroscopic methods. This applies to colloid suspensions, microcrystals, and generally to mixed systems with a fluorescent component which must not or cannot be separated. Experiments are in progress to study the absorption spectra of biological fluorescent specimens in their original state, especially in connexion with problems of cancer research. It should be noted that a 'fluorogram' records the absorption spectrum of that component of a mixed fluorescent system (for example, a solid solution) which actually absorbs the light, irrespective of which component actually fluoresces. Thus colloidal suspensions of blue fluorescent pure anthracene and of green fluorescent anthracene which contains naphthacene both gave the fluorogram of anthracene only.

This research was carried out under a grant from the British Empire Cancer Campaign. I wish to thank Messrs. Adam Hilger Ltd. and Mr. F. Twyman for the loan of spectrographic equipment.

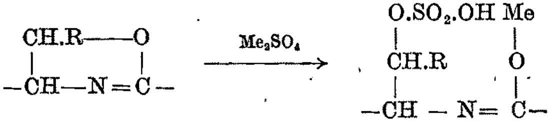
Oxazoline and Thiazoline Rings in Proteins

A study of the *O*-methylation of wool and silk with methyl bromide and methyl sulphate showed the extent of methylation could not be entirely accounted for as esterification of free carboxyl groups and we suggested that methylation of activated peptide linkages also took place[1]. We have now obtained evidence suggesting the activated peptide linkages are possibly those which have undergone condensation with the side-chains of β-hydroxy acids, for example, serine and threonine. By this condensation, oxazoline rings may arise, which Bergmann and Miekeley[2], from studies of the reactions of *O*- and *N*-benzoylserine, have considered possible constituents of proteins.



$$\begin{array}{c} \mathrm{CH.R}\text{——}\mathrm{O} \\ |\qquad\qquad| \\ -\mathrm{CH}-\mathrm{N}=\mathrm{C}- \end{array} \xrightarrow{\mathrm{Me_2SO_4}} \begin{array}{c} \mathrm{O.SO_2.OH}\ \ \mathrm{Me} \\ |\qquad\qquad| \\ \mathrm{CH.R}\qquad\ \mathrm{O} \\ |\qquad\qquad| \\ -\mathrm{CH}-\mathrm{N}=\mathrm{C}- \end{array}$$

We have now observed, in agreement with the above mechanism of methylation, that sulphuric acid is held firmly by wool methylated with methyl sulphate, and that methyl bromide, which would be less likely to open the oxazoline ring, gives less peptide methylation. We have also found that both acetyl and methyl groups can be introduced into wool, silk and collagen by the combined action of methyl alcohol and acetic anhydride. With wool, the extent of this new methylation is quantitatively similar to the peptide methylation obtained with methyl sulphate but not with either methyl bromide or iodide. For example, methyl sulphate introduced into different samples of the same wool 1·66 per cent CH_3; methyl bromide/iodide, 1·02 per cent CH_3; while acetic anhydride and methyl alcohol introduced 0·63 per cent CH_3. Hence, methyl sulphate introduced 0·64 per cent CH_3 to enolized peptide linkages as against 0·63 per cent CH_3 introduced by acetic anhydride and methyl alcohol. Methyl *p*-toluenesulphonate in methyl alcohol containing anhydrous potassium carbonate introduced 1·39 per cent CH_3 into this wool. Qualitative tests showed that some methylation of the tyrosine-hydroxyl may have occurred, but it is probable that cleavage of the oxazoline ring took place and both the peptide hydroxyl and the hydroxyl of the β-hydroxy acid were methylated.

Other evidence we have obtained suggests that free cysteine side-chains in reduced wool may form thiazoline rings in the same manner as serine side-chains form oxazoline rings, a possibility to which Linderstrøm-Lang and Jacobsen[3] have directed attention in their study of the reactions of methylthiazoline. Thus wool after maximum reduction with thioglycollic acid at *p*H 5[4] gives hydrolysates containing about half the original cystine-S as cysteine-S[5], but contrary to the findings of Harris and co-workers[4], we find that all the thiol groups in the reduced wool will not react with methylene iodide. After exposure to methylene iodide in buffer of *p*H 5, reduced wool ceases to give a nitroprusside reaction, but nevertheless, when hydrolysed yields 0·7 per cent of cysteine-S. A somewhat larger percentage of cysteine-S of the reduced wool fails to react with methylene iodide in buffer of *p*H 8. When oxygen is passed into buffer of *p*H 5 in which reduced wool is immersed, the cysteine-S is oxidized to cystine-S. If, however, the *p*H of the buffer is raised to 8, then about 0·7 per cent cysteine-S of the wool remains unoxidized, and again fails to give a nitroprusside reaction, unless guanidine is added. On the other hand, when the buffer of *p*H 8 contains guanidine, all the cysteine-S of the wool is oxidized to cystine-S. These results suggest that some of the cysteine side-chains form thiazoline rings, masking the thiol groups, which become available for reaction only to certain reagents when other experimental conditions are favourable.

Our observations have an obvious bearing on the unmasking of thiol groups when sulphur-containing proteins are denatured[6] and the increase in free reactive thiol groups which occurs when guanidine hydrochloride is added to solutions of myosin[7] and albumin[8].

Optical Projection as an Aid in Studying Plane Spiral Coiling of Small Fossil Lamellibranchs

The use of optical projection in certain screw-gauges[1] and pivot-wear meters[2] suggested methods for examining the kind and degree of variation shown by plane spiral coiling in a group of small and well-preserved lamellibranchs (*Gryphœa incurva* (Sow.)) when researches upon these variations were extended[3] in this Department recently. Identical methods proved applicable to the study of small ammonites and other shells, whether fossil or recent, provided they were coiled in a plane spiral.

It was found that an accurate lantern-slide projector gave on a suitable screen a sharply defined silhouette of any lamellibranch up to 60 mm. in diameter when the fossil was held centrally in the lantern-slide carrier on a wax or 'Plasticine' pedestal, with the plane of coiling of the shell coincident with the focal plane of the projecting lens system.

For each specimen, by appropriately altering the distance between lantern and screen and sharply focusing its silhouette, a magnified but negligibly distorted image of constant diameter was obtained, the profile of which could be traced with a pencil on a sheet of opaque white paper, or tracing paper, attached to the screen.

Using opaque recording paper, comparisons between groups of these profiles were then facilitated by cutting along the profile outlines and superposing the 'cores' so separated from the sheets. With profiles drawn on tracing paper, the superposition of chosen profiles on an illuminated tracing desk rendered their comparison even simpler than with opaque paper.

Alternatively, the profile of a particular lamellibranch was directly compared with one of several accurately plotted spirals by adjusting the diameter and orientation of its projected silhouette on an opaque white paper screen which bore a group of these curves, drawn from a common centre in black ink. The rapidity of this method was outweighed to some extent by its failure to provide the more permanent records of profiles afforded by the other two methods.

Death of St. Peter's Fish in Lake Huleh, Palestine

PALESTINE has been having some extremely cold weather and the past winter was probably one of the severest in recent years. Snow in Jerusalem and on the hills caused delight and amazement to much of the human population, but the bitter cold caused havoc and death among some of the fish in the north of the country.

In Lake Huleh, very large numbers of fish died and were eagerly collected by the local inhabitants. Altogether in three days early in January, more than 30 tons of fish were taken dead from the lake, which is a large number when it is realized that the total annual catch from the lake is only about 80 tons, of which 60 tons belong to the family Cichlidæ. It is, of course, impossible to estimate the amount of fish that died and which could not be collected, but it must certainly be large. Fish in Lake Huleh die whenever there is a very cold winter, but not on a large scale as on this occasion. The last time that appreciable quantities were killed was in 1921, but a few died of cold so recently as 1935. Usually in winter a large proportion of the fish congregate in the small rivers running into the lake and in the swampy areas around the shores. In these waters the temperature is higher than in the main part of the lake and the fish are protected from the floods of very cold water coming down from Mount Hermon.

In the past it was the custom to cut the reeds to keep the river mouths clear and so help the fish escape from the lake. In recent years, however, the reeds have not been cleared, and the river mouths are partially blocked, making it more difficult for the fish to enter. This factor may well have increased the destruction of the fish during the last cold spell. Among the dead only the family Cichlidæ, particularly the members of the genus Tilapia or St. Peter's fish, were represented, the remaining families, Cyprinidæ and Clariidæ, being apparently more hardy and able to withstand the cold. The European carp which have recently been introduced into the lake also came to no harm. Strange as it may seem, it was only the large Tilapia that were killed, though it is possible that the smaller specimens were in deeper water and the dead were not collected.

The lowest temperature recorded from the lake was 9° C., near the eastern shore. This does not seem very low, but probably the rate at which the temperature fell was more important in affecting the fish than the actual temperature. Since Lake Huleh is a shallow basin, fed by the Jordan River and by many small streams running down from Mount Hermon, and since all mountains in this region were thickly covered with snow at the time, it is probable that the water coming down was extremely cold and capable of causing local and very sudden drops in temperature in the lake, far below the 9° C. recorded.

The death of so many fish caused consternation in the country and much speculation as to whether the stock has been seriously damaged. Unfortunately it is impossible to know what proportion of the stock has been killed, for it is extremely difficult to estimate the number of Tilapia in the lake. The facts that the water is full of weeds and that much of the shore is swampy makes fishing difficult, and I do not believe that the lake is normally being fished as intensively as it should. A weight of 30 tons, or an amount equal to half the annual catch, of Tilapia is therefore probably not a large proportion of the stock as a whole. Also as only the larger fish appear to be affected and as there are huge areas of swamps, particularly in the great papyrus zone in the north, where the fish can take refuge, the damage is probably not so serious as at first appeared. Similar mass deaths must have occurred in the past during exceptionally cold years, but the lake is still well stocked and there is no evidence to suggest that the size of the stock is being reduced either by the rigours of the climate or by too intensive fishing—would that the same could be said of the depleted Sea of Galilee.

In actual fact it probably would not be a serious matter if the stock in Lake Huleh was damaged, for if the basin is likely to be drained in future, as has often been suggested, a large proportion of the fish will be destroyed in any case. Better that the lake should yield up some of its wealth now than in the future, when the need for locally produced food should not be so urgent.

Russian-English Technical Dictionary

THERE is an urgent demand at the present time for an up-to-date Russian-English dictionary of scientific and technical terms. It is known that a number of Russian-English glossaries of specific terms have been compiled by various scientific institutions and individuals, and it is thought that it would be extremely helpful to scientific workers and technical translators if copies of these glossaries could be collected together and placed in the Science Library in London, where one complete set could be consulted.

Will, therefore, any institution or individual who has compiled a glossary of Russian scientific or technical terms, whether printed or in manuscript, please send a copy to the Secretary, Anglo-Soviet Scientific Collaboration Sub-Committee, The British Council, 3 Hanover Street, W.1, who will collect these for the Science Library.

It is hoped at a later stage to compile a large dictionary, but the immediate aim is to collect the different glossaries in one place where they can be consulted. Each glossary will be known by the name of its compiler.

E. J. RUSSELL
Chairman,
Anglo-Soviet Scientific
Collaboration Sub-Committee.

A RELATIVE CENSUS METHOD FOR BROWN RATS (*RATTUS NORVEGICUS*)

By DENNIS CHITTY

Bureau of Animal Population, Oxford University

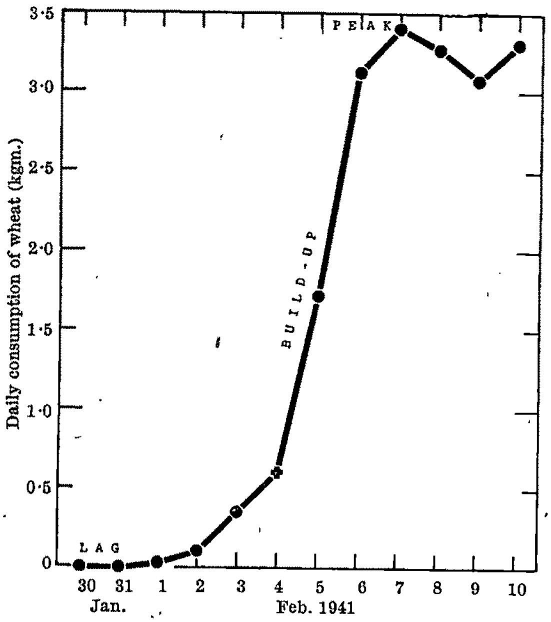
A USEFUL summary of census methods for mammals has been given by Dice[1]. Apart from those which involve killing the animals the following types have been used: counts of droppings, tracks, homes, or the animals themselves; live trapping followed by marking and releasing. Live census methods for rats have not, except in ship deratization work, been well developed along these or other lines. *Droppings* are the most reliable signs used by inspectors on board ship[2]; and their estimates of infestation usually check very closely with numbers found dead after fumigation[3]. The operation, however, is a highly skilled one, and since allowance must be made for the type of food and rate of desiccation of the droppings, probably cannot well be applied elsewhere. *Tracks* and runways in mud, dust, snow, etc., show rat distribution but give little indication of numbers. A white powder such as plaster-of-Paris is useful for showing up footprints. *Homes*. In habitats such as hedge banks a count of holes may be made; but in buildings the number is seldom related to the density of the rats. Nests of *Rattus rattus* subspecies can be seen in the trees in Hawaii[4,5] but nests of brown rats are not as a rule easily found. *Brown rats themselves* are largely nocturnal, and no representative fraction of the population is likely to be seen (on ships not more than one in twenty)[2] except by destruction of the habitat or by bolting the rats with gas or ferrets. (The method is not good in premises such as shops.) *Live trapping*, marking and releasing has been carried out at this Bureau, but involves a good deal of work and technical difficulty. *Other signs* of the presence of rats include their odour, damage to food and structures, the black, oily smear left along runways and an occasional dead rat[2].

Prebaiting for one or more days is a well-known system of rat control, but usually only small amounts of prebait are laid before the same food is given with poison added. We have termed this system 'token' as distinct from 'surplus' prebaiting which, so far as is known, has only been used before in Hawaii. Here Pemberton[5] and Doty[6] discovered that when prebait was given in excess the take increased daily for about a week as more and more rats were attracted (chiefly *Rattus norvegicus* and *R. hawaiiensis*). By mapping the distribution and amount of poison bait afterwards eaten, Doty showed the relative distribution of rats in the cane fields. In its essential features this author had already described a type of feeding behaviour discovered independently a few years later at Oxford.

Surplus baiting has been developed here as an essential part of rodent control research for the Agricultural Research Council, in the course of which it has been necessary to obtain accurate field measurements of relative population density. Wild brown rats are offered more wheat than they can eat, and, as a rule, their maximum daily consumption is used as the index of relative abundance. Wheat, which is eaten with little waste, has provided a standard medium without which these experimental results could not have been obtained. Oats and barley are less suitable as they are husked, and meals are more subject to the effects of weather and are bulkier to carry.

Fig. 1 is a typical curve showing consumption of wheat by brown rats at a prebaiting point on a rubbish dump. A 'lag', sometimes up to twelve days, may be expected before the start of feeding if the prebait is put under newly placed cover (here, an old tin trunk was used). This delay is chiefly due to rats' intense suspicion of alterations to their environment. 'Build-up': the number of prebaited rats increases for several days and a 'peak' rate of feeding is reached which is seldom exceeded unless the colony is being reinforced by breeding or immigration.

Storing. Certain types of food are stored by rats, but we have no evidence that this has happened when wheat is used as prebait, though mouthfuls may be taken away and eaten nearby. Even at places where baiting was carried on for weeks at a time no stores were ever found, and frequently after the supply had been reduced for a day the take was temporarily increased when surplus was again provided. This and other evidence of hunger shows that no important food reserves had been collected. Also if the bait is changed to a non-portable type such as wheatmeal the daily consumption is about the same.



CONSUMPTION OF WHEAT BY BROWN RATS AT A PREBAIT STATION PLACED ON JANUARY 29, 1941, ON A RUBBISH DUMP. DAILY CONSUMPTION IN GM. AS FOLLOWS: 0, 0, 30, 108, 350, 600 (NO SURPLUS LEFT), 1,710, 3,127, 3,402, 3,270, 3,077, 3,306.

Fraction of population prebaited. From the fact that a whole population can be poisoned from properly placed stations it is concluded that all the animals can be prebaited.

Proportion of prebait in total diet. This no doubt varies from place to place, and temporary drops in take after the build-up are probably due to other foods being discovered; but as a rule the fluctuations are surprisingly small. In a few cases more attractive forms of prebait must be used than wheat; but except where large amounts of food are stored without protection, as in ricks and certain warehouses, no difficulty is found in getting rats to take the bulk of their food from stations conveniently placed and regularly supplied with wheat. For example, in a certain restaurant extensive damage was being done until, after surplus baiting was started, the rats confined their attention almost entirely to the wheat.

Wild rats' consumption of prebait (per kgm. body weight) is being compared in different environments and with the amount eaten in captivity. A number of rats are trapped alive from a prebaited population and the subsequent drop in take is attributed to their removal. The rats are weighed, sexed and fed for a few days in a large outdoor cage. Experiments in progress may make it possible to convert the present relative census method into one giving the approximate number of rats.

Disturbance. The provision of unlimited food may sometimes alter existing conditions, and immigrants will be attracted if the baiting points are not, as they should be, spaced out to cover the whole colony at once. A fluctuating food supply is frequent among rat colonies and short periods of prebaiting seem unlikely to produce results that will invalidate the census or disturb the population. If token baiting is carried out during the build-up period, a surplus need only be provided for two or three days afterwards.

Specificity of the method. Animals other than rats and mice (the latter, when present at all, eat relatively little) can be kept from the bait by providing cover such as a large box with a 3-in. diameter hole; but it is most convenient to use small containers of a standard design developed by the Bureau.

Summary. A method of relative census for brown rats consists of measuring the feeding capacity of the population. It is simple to carry out, applicable in a wide variety of habitats and involves a minimum of interference with the rats. No other suitable technique is known that does not involve killing the rats. The method should be applicable to other populations which consist of only one species of small mammal.

FUTURE OF TRANSOCEANIC TELEPHONY*

TELEPHONY was born from telegraphy by an expansion of the band of frequencies employed in the electrical transmission of intelligence. More recently, further expansion has produced improvement of quality of transmitted speech and an increase of the number of simultaneously transmitted conversations. To-day, speech can be transmitted overland perfectly for any distance and with hundreds of conversations at once over a single coaxial line.

Telegraphy takes a certain band-width measured in cycles per second for a particular speed of signalling measured in words per minute. A telegraph machine printing 60 words a minute needs about 100 cycles and intelligible telephone communication requires about 1,000 cycles. 3,000 cycles for commercial telephony is now a reasonable engineering standard although it does not provide for perfect speech transmission. Speech frequencies cover about 8,000 cycles, though frequencies above 4,000 contribute little to intelligibility or quality. The range of the normal human ear is about 15,000 cycles and perfect transmission of music requires that band-width. Little is lost, however, if the music is limited to 8,000 cycles. Television requires from 20,000 cycles for a recognizable human face to 20 millions or more for vision as well defined as in standard cinema practice, but in present commercial practice the band-width is limited to about 3 million cycles.

The available frequency range of a transmission line of given band-width can be allocated to telegraphy, telephony or television at will. Twenty printing telegraph channels with adequate separation cost in frequencies about as much as one ordinary telephone channel, but for a television channel the equivalent, in frequencies, is 1,000 telephone or 20,000 printing telegraph channels.

A major advance in trans-Atlantic cable telegraphy ensued with the introduction of the permalloy-loaded cable in 1924, having a band-width many times that of corresponding non-loaded cables. The fastest loaded trans-Atlantic cable has an effective frequency band of more than 100 c./s. and can carry four times as much traffic as a non-loaded cable of the same size and length. Development of permalloy loading led to the manufacture of a 20-mile section of this type of cable in 1930, and while all the measurements in the laboratory, at sea, and from shore confirmed the technical soundness of the proposal to install such a cable, the project was postponed temporarily because of general business depression and later, indefinitely, because of the improvements in trans-Atlantic radio communication.

In the development of radio for transoceanic communication, only two isolated ranges of the band spectrum are utilized, each of which is comparatively narrow. The low-frequency range is a band some tens of kilocycles wide with a top of about 100 kc. In the 1920's the band of frequencies useful for long distances was widened several hundredfold by the discovery of short-wave transmission at frequencies in the range of 3–30 mc. This put transoceanic radio communication on its present world-wide basis. Short waves contributed also to the demand for service, since the apparatus required for short-wave circuits cost less than that for long waves.

The trans-Atlantic telephone started in the relatively cramped long-wave band and then moved into the freer region of the short-wave range. Speech was first sent across the oceans from Arlington, Va., to Paris and to Honolulu in 1915. For its accomplishment the first high-power vacuum tubes and the first master-oscillator, power-amplifier tube transmitter were evolved. In the long-wave range and for trans-Atlantic distances, radio is seriously limited in respect of the high noise-level, particularly in summer, due to thunderstorms in northern latitudes, and of the weakness of the received signals during the sunset and sunrise periods. The development of the water-cooled, high-power vacuum tube made possible high-power amplifiers to deliver tens of kilowatts needed to lift the signal higher above the level of atmospheric noise. The influence of static was further reduced by the use of directive receiving antennas. Additional improvement was provided by the technique of single-sideband transmission first used on wires. These and other developments assured fairly reliable telephone connexions and in 1927 public service was opened jointly by the General Post Office and the American Telephone and Telegraph Co. The carrier frequency was 60 kc./s., corresponding to a wave-length of 5,000 m.

---

* Substance of the thirty-third Kelvin Lecture delivered before the Institution of Electrical Engineers by Dr. Oliver E. Buckley, of the Bell Telephone Laboratories, on April 23.

The opening of the first trans-Atlantic short-wave telephone circuit in 1928 followed close on the long-wave circuit; and was followed in turn by additional short-wave circuits in 1929. Opportunities for greatly improving short-wave transmission then appeared so that the project of the second long-wave circuit was deferred and, later, postponed indefinitely. More recently, experiments have demonstrated the feasibility of transmitting two channels at different frequencies using the same transmitting equipment.

Short-wave radio gives less attenuation, lower noise and a wider frequency band in which to operate compared to long waves for transoceanic service. For a radio-telephone connexion between the United States and England the cost of short waves for an approximately comparable quality of service is about one half that of long waves. The wider band provides an opportunity for the service to expand, and it is hundreds of times wider than the long-wave band. These advantages have been reflected in the rapid growth of short-wave transoceanic telephony; at the beginning of 1939 there were in service throughout the world about 170 important long-distance short-wave telephone circuits, of which five were in regular use between the United States and Europe. There has grown up also a host of short-wave broadcasting channels, the better co-ordination of which had yet to be worked out.

Short-wave transmission, however, is susceptible to periodical interruption, particularly around the maxima of the eleven-year sunspot cycle. Short waves are also affected adversely by various types of signal distortion as the received signal is usually made up of several components which have travelled over different paths. Sometimes these paths all lie along the same great circle but involve different numbers of reflexions between the earth and the Heaviside layer. Sometimes signal components arrive over other than the great-circle path. Occasionally components travel along the longer of the two great-circle paths between the transmitter and receiver, or even clear around the world, producing 'round-the-world echo'. Interference between waves arriving over different paths results at times in 'general fading' caused by variations in the level of the whole band and at other times in 'selective fading' in which portions of the speech band are affected differently.

Single-sideband transmission has, however, helped in eliminating the periodical fading out of the carrier signal which particularly gives rise to a harsh, grating received speech. The multiple-unit steerable antenna (MUSA) recently developed in Bell Telephone Laboratories reduces selective fading by combining signals arriving over different paths or by eliminating all signals except those arriving over one path. Additional antenna directivity makes possible operation in periods of reduced signal strength, though it does not eliminate circuit interruptions at times of very severe disturbance. Single-sideband transmission and the 'MUSA' are now in regular use on the New York–London telephone circuits.

The most significant recent development in land-line telephony is that of broad-band transmission by carrier methods over open wires, cables and coaxial conductors of a considerable group of telephone bands on closely spaced channels. Over open-wire lines and over pairs in lead-covered cables, 12 telephone bands spaced at 4,000-cycle intervals are commonly transmitted in a group occupying a total band-width of 48,000 cycles. With coaxial conductors the band has been increased to 2 million cycles, giving frequency space for some 500 telephone channels, and it may be expanded still further.

The application of broad-band methods to transoceanic radio telephony are likely. Commercial success has already been achieved with small numbers of channels in the Holland–East Indies and the United States–England single-sideband systems. By applying the principles of negative feedback, Bell Laboratories engineers have developed a short-wave transmitting amplifier of 200 kw. capable of handling twelve or more closely spaced telephone channels.

When the sun is over the mid-Atlantic in summer there is available a useful band about 4 mc. wide, in the 14–18 mc. range. These short waves cannot be counted upon, however, to be duplicated very often for simultaneous use at different locations throughout the world. The available 4 mc. band must be divided therefore to meet a large number of requirements, and public service telephony across the Atlantic deserves something like a tenth of the total facilities in this band. This would mean an allocation of 400 kc. or 100 one-way telephone channels, yielding 50 or more two-way circuits realizable under the natural limitations of the medium and the other requirements placed upon it.

We can anticipate with confidence a great growth of trans-Atlantic telephone traffic, but in proportion as the demands for service grow and we come closer to the realization of the ultimate physical possibilities, the more serious becomes the threat of interruption to this service by magnetic storms.

These conclusions lead to reconsideration of the trans-Atlantic telephone cable as an auxiliary to short-wave systems. A single-channel cable would be of little value in supplementing a radio-telephone service of so many channels as there may be in the future. Moreover, the cable must also be capable of carrying a considerable group of telephone channels, and much progress has been made in that direction.

A multi-channel telephone cable to cross the ocean would have to be provided with intermediate repeaters on the ocean bottom, the repeater housing being incorporated within the cable structure. A small diameter housing incorporated as a part of the cable was therefore developed, the whole structure being so flexible that it could be bent around a cable drum.

The repeater housing comprised first a succession of pressure-resisting steel rings each having a diameter of about 1½ in. and a width of ¾ in. Over these is slid a succession of thinner steel rings of the same width but overlapping the joints of the inner rings, the whole forming an articulated cylinder about 7 ft. long. An annealed copper tube with water-tight end seals is placed over this cylinder. Within the housing the repeater elements are separately contained in plastic cylinders about 6 in. long, loosely fitting inside the inner steel rings. Connexions between these units are made with flexible conductors. D.C. constant-current power must be fed to the repeater over the cable, and an operating potential of 2,000 volts to earth, oppositely poled at the ends of the cable, was assumed. The repeater elements must rarely require attention and twenty years without replacement of parts was assumed to be reasonable. The problem of life and maintenance is principally one of a rugged long-lived vacuum tube. Ordinary vacuum tubes have limited service life on account of evaporation of material from thermionic cathodes. By making the level of transmitted signals relatively low, the space current may be kept very small and by making the cathode surface relatively large, this small current can be obtained at a temperature so low that the cathodes of the tubes may be expected to last for a very long time.

The number and spacing of repeaters depends on the length and design of the cable. For a cable 2,000 miles long to connect Newfoundland and Great Britain, forty-seven repeaters spaced 42 miles apart would provide for the transmission of a band 48,000 cycles wide.

The repeater is a one-way device and to provide two-way conversations two cables have been assumed, one directed eastward and the other westward. Assigning 4,000 cycles per channel, there would be room for twelve telephone circuits and as many as twenty-four fairly satisfactory 2,000-cycle channels could be provided.

As to the costs of such a cable for broad-band wire telephony to England via Newfoundland, even at somewhat higher annual charges than usual the total cost per telephone circuit for two cables with associated equipment would be comparable with that of prospective short-wave radio systems.

Short-wave radio links have a great advantage in affording direct connexion between points on the globe far apart, and the tendency has been to establish short-wave connexions directly between large centres rather than through extensive land-line links. The introduction of broad-band methods for transoceanic radio telephony will tend to favour centralizing radio traffic at a smaller number of more important terminals, but it is scarcely to be expected that all transoceanic radio traffic will thus be concentrated.

The world-wide transoceanic network of the future may well envisage a net comprising a large number of light linkages plus a small number of heavy linkages over the most important routes. The light linkages will represent direct short-wave single-channel or twin-channel connexions using relatively small power. The heavy linkages will comprise highly developed powerful broad-band short-wave radio systems making full use of frequency and directional diversity supplemented by broad-band submarine cables and in a few cases by long-wave radio as well.

One possible way to estimate the future for trans-Atlantic telephony is to compare the flow of telegraph traffic, say, between London and New York, with that between New York and San Francisco. Difference in community of interest is compensated to some degree by the difference in size of London and San Francisco.

This comparison may be made on the two bases of telegraph traffic, using the total number of words transmitted in a single year as the measure, and of the number of public service telegraph messages, excluding Press service, leased-wire service and code and cipher messages. In each case the estimate is based on terminating messages only. Data for the year 1937 are available and this particular year represents something between the 1929 peak and the trough of the succeeding depression.

On the first basis of comparison the total number of telegraph words transmitted over the two routes in 1937 was approximately the same. On the second basis the number of telegraph messages was about seven times as great between New York and London as between New York and San Francisco. The wide discrepancy between the two comparisons is doubtless accounted for partly by rates and partly by the character of business and social intercourse. Of the two, the second, which is based on plain-word public-service messages, appears more significant in relation to potential demand for telephone service, since public message telegraphy, as a somewhat closer approximation to the informal exchange of ideas by telephone, may be a better index of telephone demand. The potential demand for telephone connexion between New York and London is thus probably somewhere between one and seven times that between New York and San Francisco. Actually, in 1937 the telephone traffic between New York and San Francisco was about three times that between New York and London so that not more than a third, and possibly not more than a twentieth, of the potential telephone demand has been realized.

Assuming that the same ratio of potential to realized demand exists for all European–North American connexions as for the New York–London connexion, it may be estimated that 15–100 circuits will be needed across the North Atlantic depending on costs, but a demand for forty or more telephone circuits may justifiably be predicted in the reasonably near future.

To provide this increase in number of circuits, and to approach land-line standards of reliability and quality of service, all three systems—short-wave, long-wave and repeater cable—will need to be used. The bulk of the trans-Atlantic business will be handled on the short wave, but such an important service would have to maintain a higher standard of reliability than short-wave circuits alone can provide. A cable between America and Britain would provide this reliability, and it would set a high standard of transmission performance in competition with short waves.

It may not be necessary to wait until the growth of trans-Atlantic telephone business provides enough traffic to utilize fully a cable of the type described. When the engineers can give reasonable assurance of the cable it is believed that it will not have to await complete economic justification, because of the tremendous importance which it would have in ensuring privacy and continuity of trans-Atlantic telephone service.

There are already partly developed inventions which might greatly modify the picture of transoceanic telephony as set out above. One such is the 'vocoder', an instrument which dissects speech, transmits it in code and recreates it at the other end of the line. With vocoders a hundred or more simultaneous conversations might be carried by a pair of repeatered cables. While the vocoder would transmit the primary elements of conversation it would not provide all those qualities of speech which words alone do not convey. The vocoder gains in band width at the cost of naturalness of speech, but even so it may find important application.

Other inventions may extend the band-width available for transoceanic communication far beyond the range here discussed. Projects such as repeater ultra-short-wave radio systems and undersea wave-guides, which to-day appear fantastic, may some day come within the range of practicability.

THE RECORD OF PICTURESQUE BRITAIN

By DR. VAUGHAN CORNISH

THE second year's work of artists engaged in recording picturesque features of England and Wales is now on view at the National Gallery, London. This valuable work, initiated by a committee set up by the Ministry of Labour and National Service, has been made possible by a grant from the Pilgrim's Trust. It is intended that the drawings (which are the property of the Trustees) shall ultimately form a permanent collection.

A special feature of the present exhibition is a group of drawings of Windsor Castle by John Piper, lent by H.M. The Queen, who commissioned their execution after last year's exhibition. The rest of the present collection of drawings (about two hundred in number) includes examples from twenty counties, of which ten counties are additional to those comprised in last year's exhibition.

Of picturesque Buckinghamshire a charming corner house in Winslow and the red-brick town hall of Buckingham are faithfully depicted by Stanley Anderson, R.A. Notable examples of London and its environs are the Embankment, Pimlico, by Edward Walker, and The Admiral's House, Hampstead, by Norman James. Petersham and Ham in Surrey have been recorded in detail, both on account of the beauty of their seventeenth-century houses and the special risk of demolition owing to the nearness of London. Among these pictures are a general view of Ham Common, and the representation of two houses at Petersham with Dutch gable-ends facing the road.

Of towns in Hertfordshire, the steep street of Bishop's Stortford is shown in a charming pen-and-ink sketch by S. R. Badmin. The broad, open spaces of flat Suffolk are well shown in Martin Hardie's water-colour of Bawdsey Ferry.

On the western side of England, Ledbury in Herefordshire has been selected for its remarkable timber-frame houses; and, finally, crossing to Wales, Mona Moore's water-colour shows the low stone houses, of the fifteenth and sixteenth centuries, offset by a mountainous background.

In addition to buildings, the record of articles in use comes within the scope of the record of picturesque Britain. An interesting example is shown in Kenneth Rowntree's careful drawing of a coracle, the primitive boat which has come down from British times.

As this present World War goes on, we need to consider more carefully than hitherto the importance of the beauty of town and countryside in relation to the nation's welfare. When we look back to the early eighteenth century, we find the beauty of the countryside enhanced in both building and planting by the educated taste of the great landowners. Without attempting to consider the justification or otherwise of the taxation to which they are now subject, there is no doubt that if their mansions and parks be not preserved, the nation will lose one of its greatest assets of beauty. At the present time, it is of great importance to realize that an environment of beauty is no mere luxury but an essential condition for the happiness and spiritual welfare of the nation. If, however, such an environment is to confer its full benefit, the nation as a whole must be educated in the appreciation of scenery, both natural and architectural. Now that, in the twentieth century, education is no longer confined to the well-to-do classes, the proper understanding and full enjoyment of the æsthetics of scenery can be brought within the reach of all, if, but only if, the subject is brought properly before the attention of the whole community. Picture galleries are, of course, a help, but by no means sufficient. The most evident means at the command of the Government is a weekly broadcast allotted to the systematic teaching of the æsthetics of scenery.

COMMUNICATION PROGRESS

IN a lengthy article entitled "Milestones of Communication Progress" (*Elect. Comm.*, 20, No. 3; 1942), H. T. Kohlhaas presents a comprehensive review of the developments in electrical communication which have occurred within the last twenty years. In the planning and co-ordinating of long-distance telephone communication, an outstanding event was the creation in 1924 of the International Consultative Committee on long-distance telephony in Europe, following a proposal made by Sir Frank Gill in his presidential address to the Institution of Electrical Engineers in 1922. Between 1923 and 1926 a succession of recorded steps led to the establishment of the first trans-Atlantic radiotelephony circuit between the United States and England. The first Madrid–Buenos Aires radiotelephone circuit was inaugurated in 1929 and it was followed in 1930 by the first radiotelephone circuit between the Americas. In 1931 the first demonstrations of single sideband short-wave radiotelephony were carried out between Buenos Aires and Madrid and between Madrid and Paris, establishing the now well-recognized improvements in transmission efficiency and the economies which this method makes possible.

In 1931 and the following years outstanding developments in the ultra-high frequencies were described. Long-distance telephone communication was established across the English Channel on approximately 1,600 mc. using very sharp beams. Work in this general field was continued with great activity and publications appeared on propagation of these very high frequencies in 1936 and 1937, the latter including a description of the first multi-channel ultra-short wave telephone link. Later, work on ultra-high frequencies was directed also to television transmission. On one hand, there were references in 1939 to the Eiffel Tower television station delivering 30 kw. to an exceptionally long feeder over the wide band of frequencies necessary for television, and on the other, to transmission over dielectric guides at frequencies from 1,000 mc. to 30,000 mc., using various types of positive grid triodes, klystrons, magnetrons or other tube structures.

High-power broadcasting on intermediate frequencies and high frequencies took a prominent place at this period. The Prague station with 120 kw. carrier was described in 1932 and was followed two years later by the Budapest station with the same carrier power. The latter was unique for its anti-fading mast antenna over 1,000 feet high, the highest antenna ever constructed. On higher frequencies, mention was made of two British Empire transmitters added in 1937 at Daventry, rated at 50 kw. carrier power at 22 mc. Early long-distance telephone communication to ships at sea was also recorded: on the *Berengaria* in 1929; the *Belgen-*

land in the winter of 1930–31 and the *Empress of Britain* in 1931–32. Successful conversations were held with London when a ship was in the China Sea and with New York when at Alexandria. Service to the *Majestic* was opened on February 14, 1930, at first for incoming calls only.

Important work on automatic direction finders was done in 1934 and onwards and an aeroplane automatic radio compass was described in 1936. This equipment was introduced in the United States in 1937, and important experiments were made and papers published on night error and mountain effects. The subject of ground direction finders avoiding polarization errors by the use of spaced vertical antennæ with high-frequency transmission line to distant receivers was studied around 1938 as was that of aerial navigation.

Less spectacular, but fundamental, were developments in automatic telephony and transmission in which field the application of machine switching to large areas, the rapid expansion of rural automatic networks and, in recent years, schemes involving complete national dialing in some of the smaller European countries, either on a timed and zoned metering basis or on an automatic ticketing basis, were outstanding examples. These national dialing schemes led to the development of a commercially practicable system for automatic toll ticketing, each ticket containing a complete record of each subscriber's telephone call. In 1937, 1939 and 1940 a series of articles appeared showing how automatic toll ticketing was developed and introduced commercially.

The wire transmission systems went through an evolution just as remarkable as that of automatic switching. References to the first carrier telephone systems in Brazil and Australia appeared in 1924 and 1925 respectively; the first loaded and repeatered long-distance French telephone cable, in 1927; and the first twelve-channel carrier systems and the first coaxial cable in England in 1937. Several lines of development, continued year after year, are only now yielding their reward in connexion with war efforts, and this is especially true of much of the work done on aerial navigation, on direction finding and in the general field of ultra-high frequencies. This 43-page review contains much of historical interest, and concludes with a list of 159 references to papers, etc., published during the period surveyed.

FORTHCOMING EVENTS

(Meeting marked with an asterisk is open to the public)

Tuesday, July 14

Institute of Petroleum (joint meeting with the Institution of Chemical Engineers and the Chemical Engineering Group of the Society of Chemical Industry) (at the Institution of Mechanical Engineers, Storey's Gate, London, S.W.1), at 5.30 p.m.—Dr. M. Ruhemann: "The Separation of Gases".

Wednesday, July 15

Institute of Chemistry (London and South Eastern Counties Section) (at 38 Russell Square, London, W.C.1), at 6 p.m.—Dr. J. Grant: "Chemist versus Forger".

Thursday, July 16

London School of Hygiene and Tropical Medicine (at Keppel Street, London, W.C.1), at 2.30 p.m.—Prof. Major Greenwood, F.R.S.: "Civilian Hazard of Life in this War and in the Last—a Profit and Loss Account for 1915–16 and 1940–41".*

Friday, July 17

Physical Society (Optical Group) (in the Physics Department of the Imperial College, Imperial Institute Road, London, S.W.7), at 5 p.m.—Mr. F. Twyman, F.R.S.: "The Interferometer in Lens and Prism Manufacture".

APPOINTMENTS VACANT

Applications are invited for the following appointments on o before the dates mentioned:

Headmaster of the Portsmouth Grammar School—The Chairman of the Governors, Paymaster Rear-Admiral G. Grant, 4 Ol Cottages, Church Hill, Midhurst, Sussex (July 18).

Teacher of Physics, Mathematics and Engineering Science and a Teacher of Workshop Practice, in the Doncaster Technica College—The Chief Education Officer, Education Offices, Doncaste (July 21).

Veterinary Investigation Officer—The Secretary, West o Scotland Agricultural College, 6 Blythswood Square, Glasgow (July 30)

Two Demonstrators (Male or Female) in Anatomy—The Registrar, The University, Sheffield (July 31).

Lecturer in the Department of Chemistry—The Registrar, University College, Southampton (August 4).

Teacher for Day and Evening Engineering Classes, and a Teacher for Engineering Workshop Practice and Metalwork—The Principal, County Technical College, Gainsborough.

SCIENTIFIC MEN IN WAR-TIME

Strategy

FROM the outbreak of war in 1939—and indeed for a long time previously—it was obvious that the knowledge possessed by scientific men and engineers would be of decisive importance in the coming struggle. Means had to be found of making this knowledge available, and to this end the Central Register was formed. As is well known, the Register is intended to be a complete and up-to-date record of the qualifications, experience and present employment of scientific and professional men throughout the country. There have been criticisms of the extent to which it has been used, but nevertheless it must be recognized, from the figures that have been published from time to time, that it has served a valuable purpose in filling numerous posts where the special knowledge or aptitude of scientific men has been of direct service in the war effort.

As regards the senior men of science, many of them were quickly absorbed in a number of advisory committees attached to Government departments. This was, of course, no more than a development of the peace-time practice of using scientific consultants. Advice was sought and given on specific points, but it rested with officials and Ministers, often men with little appreciation of scientific developments, to decide policy and take action. The position was somewhat better where there were influential advisory councils consisting of departmental scientific advisers and eminent men of science from outside the Government service. Some of these bodies were appointed a good many years before the War, and have given valuable guidance ; among them may be mentioned the Advisory Council of the Department of Scientific and Industrial Research, the Medical Research Council, the Agricultural Research Council and the Aeronautical Research Committee. Among the war-time bodies of this character are the Civil Defence Research Committee, serving the Ministry of Home Security, and the Council for Scientific Research and Technical Development, serving the Ministry of Supply.

Still scientific men and their representative bodies had no direct voice in the formulation of policy. This defect was to some extent remedied by the formation of the War Cabinet Scientific Advisory Committee, composed of six eminent men of science, three of whom are Government servants and the other three the president and two secretaries of the Royal Society, thus preserving a balance between departmental and outside interests. The Committee, under the chairmanship first of Lord Hankey and now of Mr. R. A. Butler, reports direct to the Cabinet. A similar body under the same chairman, the Advisory Committee on Engineering, has analogous functions.

So much for the organization of scientific effort and for the means which have been adopted to ensure that sources of scientific and technical knowledge are at the country's service. But as Sir Henry Tizard pointed out in an address to the Parliamentary and Scientific Committee early this year, there are both tactics and strategy in the application of science.

Broadly speaking, the Scientific Advisory Committee, and the Advisory Committee on Engineering, with their numerous outside contacts, can exert an influence on the strategy of science; the Central Register and various departmental committees look after recruitment and tactics.

The next step is to examine the means adopted for translating strategy into action. The crux of the matter seems to be the system whereby the administrative side of Government departments exerts a disproportionate influence on the course of events. A great improvement in departmental outlook has resulted from the appointment of strong advisory councils including independent as well as departmental scientific and technical officers. The Air Ministry had long availed itself of external scientific advice, and the Ministry of Supply—which took over the scientific functions of the War Office—did the same through its Scientific Advisory Council and committees. By such means contact with the outside scientific world was ensured for their full-time workers. The Ministry of Aircraft Production took over in 1940 the scientific functions of the Air Ministry, but Sir Henry Tizard, rector of the Imperial College of Science and Technology, is a member of the Air Council as well as of that of the Ministry of Aircraft Production, and in the War Office Sir Charles Darwin has recently been appointed scientific adviser to the Army Council.

The position in the Admiralty is not so good. The Admiralty has maintained a Scientific Research and Experiment Department for many years, but its director has not the collaboration of an advisory council containing experienced outside scientific men, and the workers in Admiralty scientific establishments are far more isolated than elsewhere. Matters are improving, for a panel was appointed a little more than a year ago, containing two external scientific members, to examine the working of Admiralty establishments; and recently a group has been appointed to conduct operational research in connexion with the Naval Staff.

Although such advisory councils have done invaluable work, there is ample evidence of continued dissatisfaction with the rate of application of scientific and technical knowledge and development in the national war effort. The Association of Scientific Workers has been investigating alleged misuse of man-power and materials, and its findings are being forwarded to the Ministries of Labour and Supply, and there have been numerous suggestions in the Press for the more efficient utilization of the excellent scientific and technical resources of the country, including a revival of the suggestion for a Ministry of Science. A vigorous letter from Prof. A. V. Hill dealing with the importance of scientific and technical guidance in the highest circles of government was published in *The Times* of July 1, and succeeding correspondence has shown that his proposals have provoked wide interest. Prof. Hill says that many of our disappointments and failures to match Axis moves in the past have been due to technical mismanagement, in the sense that there has been neglect to anticipate future requirements and to profit by operational experience. The Chiefs of Staffs organization deals with operations, the Ministry of Production deals with supply; but there is no comparable body to advise the Cabinet or the Chiefs of Staffs directly on scientific or technical aspects of either operations or supply. Such a body is necessary to guide those who are directing the strategy of the present conflict. He then describes in outline the organization which has been adopted in the United States. A year ago an office for Scientific Research and Development was established under the chairmanship of Dr. V. Bush, formerly of the Massachusetts Institute of Technology, with three departments: the National Defense Research Committee (under Dr. J. B. Conant) to deal with research and development of weapons; the National Advisory Committee on Aeronautics (under Prof. J. C. Hunsaker); and the Committee on Medical Research (under Prof. A. N. Richards). This body reports direct to the President. Recently a Joint Committee on New Weapons and Equipment, consisting of Dr. Bush (chairman), one technical staff officer from the Army and another from the Navy, has been appointed, with executive authority, to work with the American Chiefs of Staffs organization, advising on technical, engineering and scientific matters, and guiding research and development in the interests of the Fighting Services.

The formation of a small body with similar powers and similar qualifications is long overdue in Great Britain. A committee or council so constituted, with high authority and direct access to the innermost councils of the State, and including adequate independent scientific and technical opinion, would be in a position to supervise the whole range of research and development coming within its field of knowledge, and to provide the co-ordination and cohesion necessary in waging a war in which the machine element plays so large a part.

Tactics

Strategy and tactics in the application of scientific developments both fail if the individual men of science are unable, for any reason, to respond to the calls made on them. To pursue the military analogy, they must keep 'fighting fit'; their minds must be fresh, active and responsive, and their knowledge must be up to date. In normal times, scientific men working in university or similar laboratories have the continuous stimulus of contact with other men engaged in diverse work, both inside and outside their own field of study; many of them spend a certain amount of time in teaching. They are members of learned and professional bodies through which the relevant literature is made available and meetings for discussions are arranged. In short, there is every facility for maintaining contact with the progress of thought in a selected field, and also with the everyday world. Workers in industrial laboratories are perhaps not quite so fortunate, in that trade 'secrets' have to be borne in mind, and they may not feel quite so free to speak in discussions. Nevertheless, it will be conceded that industrialists in general realize that research workers must be given latitude in this matter, and they usually encourage them to keep up their scientific contacts.

Scientific men in Government service are in many cases on a very different footing. In certain laboratories and establishments, notably those working under the three research councils (Department of Scientific and Industrial Research, Medical Research Council and Agricultural Research Council), they are, for the most part, almost as unfettered as are research workers in a university. Their work is usually published through the ordinary channels, and is submitted to discussion both by their own colleagues and by outside independent scientific workers. In other departments, particularly those attached to the Fighting Services, conditions of secrecy impose restrictions. It must be recognized that many of the investigations undertaken by such departments cannot be divulged, but because this is so, it does not follow that every investigation is a sealed project, and that the unfortunate individual or individuals to whom it is allotted should retire into monastic seclusion, separating themselves from their scientific brethren. Indeed by so doing, they cut themselves off from the fertilizing influence of discussion and criticism, and the quality of their work suffers accordingly. In time of war, the position is aggravated, and there is the very real danger of the administrative element taking alarm and decreeing that all work carried out in the department is secret. The proper course is to acknowledge frankly the limitations imposed by the nature of the work, and take appropriate steps to mitigate their effect.

Scientific workers in Government departments have indeed to meet special difficulties. There is grave danger of stagnation, and senior men may easily tend to become officials rather than working men of science. It is not sufficient to have a permanent scientific staff, supplemented during war-time by leading scientific workers, together with a number of temporary juniors, and to supply them with equipment and literature; they cannot develop their powers to the full in isolation. Yet this is the position in some Government Departments. It is only a reasonable precaution, at which none will cavil, that those in Government service should be expected to obtain official permission to carry on outside scientific activities; but in practice they may be actively discouraged from maintaining their contacts with the world of science.

There have been many suggestions in the past few years for improving the lot, and the efficiency, of scientific workers in Government service. The appointment of scientific advisory councils including independent scientific men, to survey progress and development in the various Departments of State, could scarcely fail to have beneficial effects. One of the first would no doubt be diminished isolation of the scientific men, particularly the younger ones, with a resulting improvement in the quality of their services to the nation. The criticism of their colleagues plays an important part in developing and maintaining at a high level the powers of scientific workers; it is an essential part of their equipment, the importance of which increases with their responsibilities.

FORMATION OF THE GANGES DELTA

Deltaic Formation

With Special Reference to the Hydrographic Processes of the Ganges and the Brahmaputra. By Prof. C. Strickland. Pp. xvi+157. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1940.) 9*s*.

WHETHER one judges by length of sea face or by distance from the apex, the combined delta of the Ganges and Brahmaputra is the largest in the world, which gives it an importance not lessened by its density of population, and its length of known history. Consequently the appearance of a work dealing comprehensively with its mode of formation and continued modification is of importance not only to geologists, but also to engineers, administrators, and medical men, and to all others who have to deal practically with the working and changes of deltaic rivers.

Much has been written in the past on various aspects of the combined delta of these two rivers and of their history as a whole, the two most important works being James Fergusson's classic paper "On Recent Changes in the Delta of the Ganges"[1], and Chapter 17, on the "Indo-Gangetic Plain", of the second edition of Medlicott and Blanford's "Manual of the Geology of India", as revised by R. D. Oldham in 1893. Fergusson is one of those rare men who have produced classics in two branches of knowledge, the other being his "History of Indian and Eastern Architecture"; and both his classics still hold the field to the present day as the most important works in their respective spheres.

No detailed or even continuous geological survey of the Ganges-Brahmaputra delta has ever been attempted owing to the paucity of geologists in India compared with the tasks; but certain of the major aspects of the Indo-Gangetic river system including the deltas have been dealt with by geologists, while some of the more detailed aspects of the Ganges-Brahmaputra delta have been discussed from time to time by settlement officers, and by engineers concerned with irrigation, drainage and river training; further, of recent years, gravity observations by the Geodetic Branch of the Survey of India, and by the staff of the Burmah Oil Company, have led to the acquisition of knowledge, not all of it published, concerning the configuration of the basement upon which the delta rests.

It is timely, therefore, that some one should attempt to synthesize the growing knowledge on this delta, especially one who has had abundant opportunity to make personal observations on the behaviour of rivers in deltaic tracts as an adjunct to his own professional work. For Dr. C. Strickland, who is a member of the professorial staff of the School of Tropical Medicine, Calcutta, has had occasion, in his medical capacity as a research worker on problems connected with the causes and prevention of malaria, to travel far and wide, not only in Bengal and Assam, but also in Burma and Malaya, and elsewhere; like Fergusson he has made full use of his opportunities to observe the detailed behaviour of deltaic rivers.

In his book the author devotes the first twenty-six chapters to the discussion of the hydrographic processes at work in the Ganges and Brahmaputra, assuming the rock basement on which the alluvium rests to be static, and reserving for a final chapter "the influence of diastrophism of the earth's crust on the hydrographic processes". The author has recognized the important geologist's separation of the alluvial deposits into 'older alluvium' and 'newer alluvium', the older alluvium being now subject to denudation and the newer alluvium still in course of deposition, either in channels in the older alluvium or on land newly won from the sea; but he prefers to describe these respectively as 'paradeltaic' and 'deltaic' deposits. This has really involved a redefinition of the term 'delta', and leads to the confusing result that patches and streaks of 'paradelta' may be mixed up with or surrounded by the 'delta', while strips of 'paradelta' are found right into the Himalaya. To me it seems preferable to retain the customary use of the word 'delta', recalling that it takes its name from the triangular shape of the Greek capital letter, and that a delta commences at the point where a river begins to divide into distributaries, this point being the apex of the delta. The deltaic tract, on this usage, then consists of portions that were formed in the past and may now be undergoing erosion, and portions where active deposition is still taking place. However, Dr. Strickland's use of the term 'paradelta' does not spoil comprehension of his work. If adjectives are required to describe the older and newer deltaic deposits, would not *palæodeltaic* and *neodeltaic* be suitable?

The main thesis of this book is that all the changes observed in a delta can be explained purely on a hydrographic basis without invoking the aid of diastrophic processes. Thus the fact that there is a belt of low-lying land occupied by numerous swamps, with *bhils* or *jhils* of water, stretching continuously from near Calcutta eastwards through the districts of Jessore, Faridpur and Backergunge, as indicated on Fergusson's map, and separated from the sea face to the south by a belt of higher land, is not, according to Dr. Strickland, due to a diastrophic depression of the swamp belt, as some engineers and settlement officers have urged, but to the elevation of the seaward belt by deposition from the distributaries of the delta, as is accepted by geologists. Also Dr. Strickland holds that such elevated tracts as the well-known Madhupur Jungle north of Dacca are merely residua of denudation and do not owe their existence to tectonic uplift. In this he disagrees with Fergusson and Oldham, and is perhaps unaware that Colonel Glennie, of the Survey of India, has recently shown by means of gravity determinations that there is a minor 'up-warp' under the Madhupur Jungle.

Dr. Strickland is working on sound lines in explaining as much as he can on a purely hydrographic basis, drawing his deductions from phenomena that are observable at the surface; but it must be recalled that the deltaic tract of the Ganges and Brahmaputra is tectonically very unstable, as is shown by the frequency of earthquakes, which in some cases, especially towards Assam, have produced results observable at the surface, as described in the relevant Memoirs of the Geological Survey of India.

Moreover, while anyone who studies the geological and orographic data can accept the view that the Brahmaputra and Ganges were once parts of a river flowing westwards to join the Indus system (Pascoe's "Indobrahm" and Pilgrim's "Siwalik River") and separated from the Bay of Bengal by a ridge of land joining the north-east corner of the Peninsula to the Assam Plateau; and that this ridge has since been breached, so that a southward-flowing river or rivers (for example, the ancestor of the Bhagirathi and Hooghly) debouching into the Bay of Bengal could cut back by head erosion and tap the Indobrahm, it does not follow that this was achieved by head erosion alone. It seems to me that diastrophic processes must also have taken a hand, and that this breach through which the Ganges and Brahmaputra now flow south is partly the result of down-faulting. According to the gravity results of the Survey of India[2] there is still an axis of 'up-warp' (by which is presumably meant a belt of rock denser than that to the north and south) connecting Bihar and Assam under the Ganges-Brahmaputra alluvium. As the back of this axis of rock, however shallow the alluvium may there be, lies presumably below sea-level it cannot have been lowered by river erosion, and must have been thrown down by tectonic movement.

Further, as the alluvium under Calcutta is known from borings to be at least 1,306 ft. deep[3] (and is possibly several thousand feet thick), and is composed of freshwater and estuarine sediments that were all deposited at or close to sea-level, the rock floor beneath the Ganges delta must have sunk by 1,300 or more feet, due either to the growing load of sediment (then an isostatic adjustment), or to direct diastrophic movement; consequently it is impossible to exclude causes other than hydrographic from the general discussion, although all surface details can be explained in terms of deposition and erosion due to hydrographic processes, as is done so lucidly by Dr. Strickland. Once the necessity of admitting the action of diastrophic processes at least at intervals is recognized, one must admit also the possibility that the Madhupur Jungle and other elevated tracts of older alluvium owe their present elevation to uplift.

Every student of river processes is recommended to study Dr. Strickland's work, wherein he will find a full discussion of the processes by which new land is won from the sea, of the formation of lagoons or *bhils* of various types and of islands (*dwips*), of the embankment of rivers, of the conflict between the transporting action of rivers and the influence of tidal waters, and of the gradual death of many deltaic river channels. In reading this book, however, he will find it necessary to make periodic reference to a dictionary, because the author uses many uncommon words, or gives them unusual meanings, such as "appose" and its derivatives, "occlude" and its derivatives, "declivity", and "infinitesimally great"; or uses words that do not appear to have dictionary sanction, such as "alluviation", "diluviation", "siltation"; while the word "height" is consistently spelt with a final "h". But these difficulties are alleviated (or shall we say "alluviated"?) by a racy style and free use of happy metaphor, as in the following quotation, which illustrates the spirit of the book (p. 4): "Therefore no alluvial deposit has any 'divine right' to permanency, simply because it was once thrown down by a 'wet nurse' who could bear the burden no longer."

L. L. FERMOR.

[2] Geodetic Report, Survey of India 1937, Chart IX.

[3] See Dr. A. L. Coulson's "The Geology and Underground Water-Supply of Calcutta, Bengal, with special reference to Tube-Wells", *Mem. Geol. Surv. Ind.*, **76**, 24 (1940). This work is contemporary with Dr. Strickland's book, and neither author appears to be aware of the other's work. Chapter 2 of Dr. Coulson's memoir gives an excellent summary of previous work on the "Early History of the Ganges and the Formation of the Ganges Delta".

A PHILOSOPHY OF THE UNIVERSE

Design and Purpose

By Prof. Frederic Wood Jones. Pp. 84. (London: Kegan Paul and Co., Ltd., 1942.) 5*s.* net.

IN this little book, an expanded version of his Purser Lecture at Trinity College, Dublin, Prof. Wood Jones expresses his general philosophical convictions. The whole universe, he argues, forms one system, a chain of being including both the animate and the inanimate. Man has his place in the system along with all other creatures and is in no way apart from or above it. The system is not to be considered as a mechanical aggregate but as exhibiting design throughout and as the sphere of purposive action; as, in fact, the outcome of the creative purpose of the cosmic mind. The author invokes, in support of his view, the animism attributed to primitive man, the systems of Buddha and Lao Tze, and also of Plato and Aristotle—rather a mixed bag of authorities.

What is more surprising is that Prof. Wood Jones also invokes the support of Paley. For Paley surely, like practically all those of his time, was arguing for a purely mechanical universe in which living organisms were just more elaborate and automatic machinery, and all was designed and run by the Great Artificer. It may be granted at once that Paley was more clear-sighted than many of the Darwinians of a later day who supposed that automatic machinery could somehow design, produce and run itself by pure luck, coupled with the blessed word 'evolution'. Still Paley stands for two doctrines that are otherwise anathema to Prof. Wood Jones. As to the first, Paley's system was not conceived in terms of a theory of pantheism or of a purely immanent world spirit, such as Prof. Wood Jones approves, but in terms of a personal and transcendent deity. That is a view that Prof. Wood Jones attacks fiercely, seeing nothing in it but an unfortunate survival of the tribal god of the ancient Hebrews. Clearly you can have either a mechanical world run by a transcendent mechanic or the world as organism animated by a world soul. By itself each is a reasonable view, but the two are not easy to reconcile; certainly the advocate of one can scarcely claim the support of the advocate of the other.

The second difference is that Paley, necessarily as a Christian, held that the human soul is in some way separate, distinct from and above the material and mechanical world. Plato also held this view, though he did not believe in a mechanical universe. For Prof. Wood Jones such a theory savours of false pretensions and arrogance. There is a very dangerous kind of humanism which puts man above Nature, and it has been very prevalent since the Renaissance. Against this his attack is well and properly directed, but it has nothing to do with Christian or Platonic theories about the soul, which are perfectly compatible with his view, and which I believe he misunderstands. His point may be put quite simply. Analytic, sophisticated urban thinkers tend to imagine man as something separate from his environment, superior to it and therefore entitled to interfere with other creatures to make them serve his own ends. A true appreciation of the facts comes easily to man living under primitive conditions. The facts were clearly seen by synthetically minded thinkers of earlier times. The same lesson can, however, be equally well learnt from biological science when the view of the whole is not obscured by partial views of mere specialists. If we realize that organism and environment are inseparable and each adapted to the other, that men like all other creatures have a part to play in a cosmic purpose greater than any individual, then we are likely to take a humbler and more balanced view of ourselves. This is worth saying. In this connexion Prof. Wood Jones does well to remind us of Samuel Butler, even though Butler's biology was not always very sound. It is true that science in the strict sense can tell us nothing about a cosmic (or any other) purpose; it is a metaphysical notion. It is also true that if there is no kind of cosmic purpose, then the purposes of individual human beings are futile.

A. D. RITCHIE.

ECONOMIC FORCES AND WORLD ORDER

The Economics of 1960

By Colin Clark. Pp. x+118. (London: Macmillan and Co., Ltd., 1942.) 8*s.* 6*d.* net.

MR. COLIN CLARK is easily the most daring of statisticians. We have known since he published his "Conditions of Economic Progress" that there is almost no degree of inadequacy in the data that is enough to deter him from arriving at some sort of a quantitative conclusion, however provisional it has to be. In his new book he applies to the future the methods he has made his own in handling the present and the past. His general thesis is that the course of economic development over the next two decades will probably be affected very little by political events. War may retard the processes of growth, but will scarcely alter their character; and changes in social system and class structure can also be disregarded in measuring the probable movements of the world's economic life. In the past, Mr. Clark maintains, wars and revolutions have been unable to override fundamental economic forces; and we and our children are likely to find it so again.

To be sure, Mr. Clark postulates, for the purpose of his prophecies, a world not dominated by economic nationalism, and a freedom for the exchange of commodities and services in marked contrast to the tendencies of the past twenty years. But he seems to think that this freedom will be forced on the world by economic forces, whatever politicians may plan. His thesis is that historically economic development reveals an alternation of 'capital-sated' and 'capital-hungry' periods, and that, after a period of satiety, the world is due to pass into a period of capital-hunger which will be intensified by war-destruction. He therefore looks forward to a very active resumption of international investment, accompanied by, and indeed involving, a big shift away from primary production to manufacturing and service industries, as well as a sharp alteration in the 'terms of trade' in favour of primary producers as against manufacturers.

These shifts, he believes, will be part of a process which will add immensely to the world's total wealth and especially to the productivity and income of the countries which are behindhand in economic development. He expects China, India, Eastern Europe and other backward areas to absorb huge masses of capital and, while becoming industrialized, to become at the same time greatly improved markets for the consumers' goods as well as for the capital goods of the already developed countries. He expects not only the United States, but also the U.S.S.R., to become a large net importer of foodstuffs and other agricultural products, and advances notions which are at first sight startling about the economic future of many other areas. His arguments are backed up by the clear demonstration that the immense changes which he confidently predicts are no bigger than the changes which actually occurred during the nineteenth century under the impact of the Industrial Revolution.

A large part of Mr. Clark's book is statistical; and many of his calculations refer back to his "Conditions of Economic Progress", and cannot be fully understood without looking up the relevant passages of that work. Indeed, "The Economics of 1960" is in form a sort of forward-looking postscript to his "Conditions"; and critics who were sceptical of Mr. Clark's methods in the main book are likely to be no less sceptical now. I confess, myself, to a certain degree of scepticism, combined with a conviction that Mr. Clark is essentially right. I do not believe in many of his figures; but I do believe that he is correctly predicting the trends, if not their absolute or relative strength. There can be no doubt either that the world is ripe for a vast new adventure in international capital development, based mainly on the rapid industrialization of Eastern Europe, Asia, and parts of Africa, or that this new phase of growth requires a politico-economic setting of unrestricted, though not necessarily unregulated, foreign trade. If the political settlement after the War is of such a character as to frustrate the exchange of goods and services, there will be a terrific conflict between the forces sustaining the settlement and the forces making for a world crusade against poverty and unemployment. Mr. Clark seems to be entirely confident that in this struggle the forces of unreason would get the worst of it. I sincerely hope they would; but I am not so sure—and I am still less sure that the basic economic forces will win quickly enough for all the gains Mr. Clark has in mind to have been safely garnered by 1960.

I am therefore disposed to accept this statistical pamphlet less as an essay in prophecy than as a pointer towards a sane world economic policy. For I think Mr. Clark has been able to show quite conclusively that the world can, if it behaves itself with ordinary common sense, be by 1960 immensely more prosperous than it has ever been, and that too with a prosperity shared in by most of the human race. Regarded in this way, Mr. Clark is a powerful ally of Mr. Roosevelt, Mr. Wallace, and other American spokesmen of the age of plenty, and a formidable critic of the economic restrictionism which has been so terrifyingly enshrined in recent pronouncements of the Federation of British Industries and other representative organizations of British capitalism. Certainly, if these apostles of monopoly get their way, Mr. Clark's predictions will not be verified. Rational division of labour between areas will be prevented; international investment will not revive; there will be mass-unemployment as there was in the 'thirties, and probably yet more and more devastating war. Mr. Clark, I think, will agree to this, but will reply, more confidently than I can, that the restrictionists will not get their way, and that, war or no war, the underlying forces making for economic progress will get theirs. I am not so sure as he is that our civilization is indestructible by human folly. But I earnestly hope that he is right; and I welcome his book as a most cogent dramatization of what mankind is in a position to accomplish in the economic sphere, if mankind but will. G. D. H. Cole.

A POPULAR INDEX TO COLOUR

Horticultural Colour Chart

Vol. 2. Issued by the British Colour Council in collaboration with the Royal Horticultural Society. 100 plates. (London: Royal Horticultural Society, 1942.) 12*s.* 6*d.* to Fellows of the Society; 22*s.* to non-Fellows.

An abnormal three years have intervened between the publication of the first volume of the Horticultural Colour Chart (reviewed in Nature of March 11, 1939) and the recent appearance of the second volume, and the publishers are to be congratulated on the foresight which led them to reserve the art paper and other materials required to ensure uniformity of make-up.

Thirty-four of the new sheets show lighter tints, twenty-eight selected darker shades, and the remaining thirty-eight plates are taken up with hues greyed to a lesser or greater degree. (Twenty-six sheets of the first volume represented paler tints, and ten darker shades, of certain of the sixty-four full hues.) The extent to which the brightness or purity of the full hue is modified is indicated by an appropriate prefix to the sheet reference number of the unmodified colour. A complete series on these lines would require a great number of sheets, and convenience and cost alike demand a reduction to more manageable proportions by selection of the most useful modified or supplementary colours. The publishers imply, although they do not specifically state, that this second volume is final.

A random selection of flowers picked during March–June showed the chart as a whole quite efficient in providing close colour matches. It fails in some cases. Many Polyanthus have flowers outside its range, particularly in dark shades; Viola and other genera, including dark and velvety-textured flowers, discover the same lack of matching sheets. The bluest primroses would require the appropriate hues to be twice or thriced greyed in the scheme of the chart, whereas they are only represented once greyed, if at all. By a process of imaginative intercalation or extension such gaps can be filled, and a non-existent sheet number quoted as a guide to the required colour, if not as a certain match. Browns are ill-represented. This weakness is perhaps not important where flower colour is concerned, although it will be noticed, for example, in connexion with Fritillaria; but greater curtailment of the usefulness of the chart in other spheres will result.

The "horticultural examples" given on the sheets are not always happily chosen. The flowers of *Aquilegia vulgaris* as a wild plant vary considerably in hue, and in the garden show a whole gamut of colours of which the "aconite violet" singled out for quotation is doubtfully the commonest. Similarly injudicious references are *Saxifraga oppositifolia*, *Primula denticulata*, *Dianthus barbatus*, and *Geranium sanguineum.*

The most serious faults of the chart were already obvious in the first volume. There is considerable but inconstant overlap between tones of the same hue on different sheets; 928, for example, appears quite redundant, as 828 and 1028 form a continuous series without appreciable break; the range of colour on 403, 503 and 603 could comfortably be accommodated on a single sheet. If this kind of duplication had been avoided the same number of two hundred plates could have covered most of the omissions mentioned above.

A common lilac (*Syringa vulgaris*) is placeable with equal propriety against 437 or 537/2; but its colour would accordingly require naming pastel lilac or (pale) mauvette. In the same way *Scilla bifolia* may be (pale) gentian blue or flax blue. Quite apart from the alternative classifications made possible in this way, unrelated colour names within the confines of a single hue are a mistake. If independent names had been restricted to the sixty-four full hues (relaxing this rule in favour of brown and pure grey), and, to take a set at random, sheets 622, 22, 022, 0022, 722, 822 had been named pale crimson (or crimson pink), crimson, dull crimson, grey crimson, rich crimson, deep crimson, instead of camellia rose, crimson, rose opal, rhodonite red, cherry and cardinal red, not only would relationships have been made obvious, and despite overlapping, serious ambiguity avoided, but also actual use of colour names in a uniform sense would have received far more encouragement than will be given by the chart in its present form. Utility has been sacrificed on the altar of 'historical interest', and the best possible use not made of good work.

For the chart itself is good work. Perfection has not been attained, of course; the tone intervals are not constant in the treatment of different hues, and changes in intensity (purity or saturation) occur where nominally only a tone difference exists. But obvious fault is very rare, and the ink makers and printers are to be congratulated on a fine technical achievement.

SAMPSON CLAY.

SOME ASPECTS OF PHYSICS

Reports on Progress in Physics

Vol. 8 (1941). General Editor: W. B. Mann. Pp. iv+372. (London: The Physical Society, 1942.) 25*s*. net.

THE years since the outbreak of war have seen an unprecedented increase in the number of men actively engaged on research in physics, using the word 'research' in the sense of the application of the principles of physics to the solution of urgent practical problems. New research establishments have been created, old ones greatly extended, and students are being rushed through universities and technical institutions to give a hand with the work, or to service the inventions which have already reached the stage of production. That this expenditure of energy and ingenuity is not going unrewarded is well known, though, for obvious reasons, nothing of this activity can yet find its way into "Reports on Progress in Physics", the eighth volume of which (1941) is now to hand. When the time comes to raise the veil of secrecy which now necessarily hides the war-time activities of physicists from the common gaze, the editor of these Reports will be in for a good time: for it can scarcely be doubted that much of permanent interest will emerge from these *ad hoc* investigations. In the meantime he undoubtedly has his troubles. Not only has fundamental research been replaced by war-time activities, but also likely authors are too preoccupied to report even on immediate pre-war discoveries. That, in the circumstances, the new volume should have appeared so promptly, and, in appearance and format so like its elegant predecessors is an achievement on which the Physical Society, and the new general editor, Dr. W. B. Mann, may be sincerely congratulated. That, in addition, it should contain three or four reports of real interest is an uncovenanted mercy for which we may be duly thankful.

For this admirable result the editor is much indebted to the generous help of American physicists, who have contributed more than half the text, and considerably more than half the interest of the volume. At the time when the reports were planned the shadow of war had not actually engulfed the United States, though it was obviously approaching fast. Physicists there had just time for one further look round the laboratory before taking off their coats and settling down to the job; and they have certainly made the most of the opportunity. That they should, as the editor records, have also requested that the honoraria attached to the reports should be given to some suitable fund in Great Britain is only one further example of the large-hearted sympathy which American men of science have so consistently shown towards us throughout our struggle. We shall not easily forget it.

To present a completely impartial account of a collection of fourteen separate reports on a wide variety of topics is probably beyond the power of a human physicist; no doubt some ingenious combination of photo-cells and electronic valves will ultimately be designed to do the job. In the meantime judgment is certainly influenced by personal interest in the subject-matter of the report. In particular, a wide and ever-widening chasm seems to be opening up between the experimental and the theoretical physicist. Much as we may agree with Prof. Born (whose article on the "Teaching of Theoretical Physics" opens the volume) that "the separation of one single science, physics, into two parts which differ, not with respect to the object but with respect to the method" is particularly regrettable, it must be confessed that neither party is much interested in the other's technique, and that neither the language nor the modes of thought of the theoretical physicist are easily comprehended by his experimental colleagues. To ask that the theoretical physicist should write for the benefit of the experimentalist would be to deprive his report of much of its intrinsic value. A subject which, to quote Prof. Born again, requires only "paper, ink, pen, a few books, and a calculating machine" is likely to be popular in the days of austerity after the War; unless, of course, one of the 'planning' committees for which some of our enthusiasts are pressing should decide that the subject is anti-social, and order its suppression. May we offer the suggestion that, when times become easier, the Physical Society might consider the possibility of issuing separate Progress Reports on the two aspects of our vast subject; employing some specially gifted person—Prof. G. Gamow could do it—to report to the experimental physicist as much as he needed to know of the contents of the theoretical volume.

Descending from the general to the particular, every physicist will be glad to have at hand Raymond T. Birge's latest report on the "General Physical Constants", and the tabular results of his latest survey of this fundamentally important subject. Incidentally we may hope that the powers that be (if there be any "powers" in physics) will take note of the fact that, owing to the coexistence of international coulombs, absolute coulombs, a chemical scale of atomic weights and a physical scale of atomic weights, Birge finds it necessary to give four different values for the Faraday constant, and decide to do something about it. George R. Harrison gives a fascinating account of the M.I.T. project for measuring and tabulating the wave-lengths of some million spectrum lines—an example of mass production in high accuracy measurement which in ingenuity and courage can bear comparison with anything achieved in industrial mass-production. J. W. Beams contributes a useful summary of advances in "High-speed Centrifuging"; and "Recent Television Developments" are dealt with by V. K. Zworykin and R. E. Shelby, of the R.C.A. and the National Broadcasting Company, New York. On the theoretical side, Robert S. Mulliken and Carol A. Rieke report on "Molecular Electronic Spectra", and Eugene P. Wigner and Eugene Feenberg discuss the "Symmetry Properties of Nuclear Levels".

It would be unreasonable to expect that all the reports in the volume should reach the level of interest of those named in the previous paragraph. R. W. Lunt, with von Engel and J. M. Meek, gives a useful summary of the present position as regards discharge phenomena in gases, leaving one with the no doubt justifiable impression that there is still a good deal to be cleared up in the subject, and A. Hunter contributes a readable account of recent improvements in instrumental technique in astrophysics. If some of the remaining contributions scarcely seem to come up to pre-war standards (and it must be admitted that one or two of them are a little weak) we must lay the blame on the times. "Reports on Progress in Physics" has established itself as the most important yearly publication in the subject. In spite of difficulties, the present volume as a whole does nothing to impair its reputation. May we wish the Society and the editor equal good fortune with Volume 9. J. A. Crowther.

A FATEFUL LEGACY

Darwin, Marx, Wagner

Critique of a Heritage. By Jacques Barzun. Pp. xii+420. (London: Martin Secker and Warburg, Ltd., 1942.) 15s. net.

Mr. Barzun is a historian who is especially interested in the political effects of theories of race and class conflicts. He has already published works on "The French Race" (1932), "Race: A Study in Modern Superstition" (1937), and "Human Freedom" (1939). His researches have convinced him that the terrible predicament in which mankind now finds itself is mainly the result of the influence of certain ideas set in motion by three men in the second half of the nineteenth century—including under 'influence' also reactions against them. The three thinkers in question were Darwin, Marx and Wagner. At first sight this may seem a curious combination. The author may appear to have been impressed unduly by his observation that it was in the same year (1859) that Darwin published "The Origin of Species", Marx his "Critique of Political Economy", and Wagner completed "Tristan and Isolde". Whether this was or was not a mere coincidence, Mr. Barzun makes out a plausible case for his view that, in spite of their obvious differences, the three authors expressed and popularized one and the same philosophy, namely, that of mechanistic materialism. Darwin did so in the field of natural science, Marx in that of sociology, Wagner in that of art.

The possibility of a common world view, amid their divergent specialisms, was facilitated by the fact that none of the three men stuck strictly to his last; they all spread themselves more or less widely beyond their special province. Darwin had much to say about psychology and social science; Marx exercised the privilege of a philosopher, and took all the world to task; Wagner wrote more than he composed—in fact his writings fill ten volumes, and deal with all sorts of things.

Mr. Barzun also detects some common traits in the characters of the three men. He contends that they were all rather self-centred, ungrateful to their forerunners, and ruthless to their rivals and critics. Many who would readily agree with this view of Marx and Wagner will probably demur in the case of "our gentle Darwin". Mr. Barzun, however, submits a considerable amount of evidence in support of his contention. Some of the evidence may be indicated briefly. Darwin somehow conveyed the impression that he had arrived at his conception of evolution independently of his predecessors and contemporaries, although it is known that he was acquainted with the work of Buffon, Lamarck, Malthus, and his grandfather Erasmus Darwin. The "Historical Sketch", which was first added to the third edition of "The Origin of Species", dismisses Buffon, misrepresents Lamarck, and buries Erasmus Darwin in a footnote. Yet, according to Osborn, Darwin's theory of the origin of species was really threefold, and two of these component theories were adopted from Buffon and Lamarck.

Be this as it may, Darwin's main contribution to the theory of evolution was, of course, his theory of natural selection from accidental variations. Variations favouring survival are preserved. But the variations are accidental, and the selection is natural or automatic. So the changes in living forms appear to be accounted for in a more or less mechanical way. Nature red in tooth and claw did not disgust Darwin. He could even see grandeur in this struggle for existence. "From the war of nature," he wrote, "from famine and death, the most exalted object of which we are capable of conceiving, namely, the production of the higher animals, directly follows. There is grandeur in this view of life." It was obviously easy to misapply such a view to politics. People saw grandeur in war and other forms of political and social conflict. The literature of the period 1870–1914 is one long call for blood. In almost every European country during that period there was a war party demanding armaments, an individualist party demanding ruthless competition, an imperialist party demanding a free hand over backward peoples, a socialist party demanding power, and a racialist or nationalist party demanding purges of aliens. Of course, Darwin would not have approved of such applications of his view. In fact, he soon began to have doubts about the efficacy of natural selection even among races of pigeons, let alone races of men. But ideas once set in motion soon get out of the control of the originator, and continue to be misapplied by unscrupulous opportunists in ways that sometimes make science a source of mortal danger to mankind.

Marx regarded himself as the Darwin of sociology.

He wanted to dedicate his "Capital" to Darwin, who, however, declined the honour without interest. Social development appeared to Marx to be essentially similar to natural evolution. Both are determined by material factors; and the individual does not count in either case, only the class. The material factors in the case of the social group are the natural resources, modes of manufacture, means of communication, etc., which constitute the social environment; and the social struggle for existence takes the form of a conflict of classes, through which progress is achieved. Marx, however, was not content to leave things to 'natural selection'. He resorted to fierce propaganda, fanatical agitation, and ended as the "Machiavelli of the working class movement".

Of the three characters who occupy Mr. Barzun's stage, Wagner was undoubtedly the most mischievous. He was selfish and opportunist in the highest degree; and as a born actor he managed to appear better and wiser than he was. His music-dramas, like his life, are mainly concerned with fighting, deception and adultery; and his use of old pagan legends and a creed of fatalism was a device to put at least a thin veneer of respectability on the immoral. Nietzche saw through him and denounced him. The militarists, however, found in Wagner just what they wanted, especially in his "Ring", which celebrates the superman and the triumph of Germanism, in a tale of blood, lust, and deceit. Wagnerism became a widespread cult. German soldiers and politicians fancied themselves bestriding this world like the legendary gods and heroes of Wagner's stage. They were intoxicated by Wagner's art and his artfulness, and were stimulated in the pursuit of ambitions which for the second time in a generation are threatening to devastate mankind.

Mr. Barzun's book is not entirely free from mistakes or from an occasional tendency to journalism; but it contains a vivacious and competent discussion of many interesting problems, and may be recommended to all who are interested in our heritage of fateful ideas. A. Wolf.

ENGINEERING PEDAGOGY

Engineering Mechanics

By Prof. S. Timoshenko and Prof. D. H. Young. Second edition. Pp. xiv+523. (New York and London: McGraw-Hill Book Co., Inc., 1940.) 28*s*.

Engineering Kinematics

By Prof. Alvin Sloane. Pp. xi+310. (New York: The Macmillan Company, 1941.) 17*s*. net.

In the training of the young engineer the teacher has to look both backwards and forwards. He has to examine carefully what has been done in the past, that his students may master the detailed technique already applied successfully in these problems. In this respect he seeks to produce young men capable of dealing with issues similar to those previously solved. On the other hand, he knows that every problem is in reality a new problem with characteristics that are different from those previously encountered. For this purpose facility with technique may not in itself suffice. What may be required is a new application of fundamentals, or a search for new generalizations from the past, to be applied in a new way.

Text-books on mechanics and kinematics therefore have two functions to fulfil. They require to present a detailed course primarily designed for improving the facility of the student in solving problems of an orthodox nature; or they may provide a reorganization of existing knowledge in new ways to throw up the underlying new principles to be found applicable to the future.

These two books, each in its own way and in its own field, deal with these separate issues. Profs. Timoshenko and Young, in this the second edition of their "Engineering Mechanics", have produced a first-rate text-book covering all the elements of statics and dynamics that fall within the scope of an orthodox set of courses—the principles of statics, concurrent and parallel forces in a plane, forces in space, virtual displacements, applications of Newton's Laws of Motion to particles and to rigid bodies, including some treatment of the gyroscope.

The illustrations throughout, although in the academic form usually associated with university courses, keep close to engineering practice. They are exhaustive, covering in each section almost every type of problem that arises, while a multitude of diagrams, clearly produced, serve to ease the development for the student. There are approximately 600 examples, many of them worked out in detail. Any student who has worked through this book will have received such a grounding in the application of orthodox dynamical principles that he will find no difficulty with the more specifically engineering problems that arise in other parts of his course. The book is excellently produced.

The other line of approach to which we have referred is stressed in Prof. Sloane's treatment of engineering kinematics. While the general headings are simple and straightforward—the rigid body, vectors, motion, displacement, velocity and acceleration—throughout the work there runs an underlying philosophical current to the book, and the fundamental concepts are critically examined and developed in a way that must be attractive and interesting to the student. Naturally a great deal of its scope is covered or implied by the previous book by Timoshenko and Young, but there is a great advantage to the budding engineer in his understanding of the principles of mechanism in being forced to study the classifications into which the multitude of mechanical devices can be subsumed. Definitions that seek to distinguish between mechanisms, machines, and instruments, for example, and so enable the wide variety of gears, cams, and linkages to be classified for their similarities and their differences, enable the author to bring out law and order throughout the whole of his text where otherwise diversity only tends to be seen. The simple headings of his chapters, already referred to, side by side with the many diverse types of illustration that fall within these heads, serve to underline this point.

It will be seen, therefore, that the particular virtue of this book lies not so much in the choice of material from the field usually covered in courses on mechanism, but rather in the pedagogical method of approach which fosters an appreciation of the common kinematical background. Like the previous book, the publishers are to be congratulated on their excellent production in paper, printing and diagrams.

Motor Vehicles and their Engines

Fifth edition, by Norman G. Shidle and Thomas A. Bissell, with the assistance of Tench Francis. Pp. vii+339. (New York: D. Van Nostrand Co., Inc.; London: Macmillan and Co., Ltd., 1941.) 16*s*. net.

FOR the student who is interested in learning to do practical repair work on motor-vehicles, the first consideration is that he should obtain a comprehensive knowledge of the construction of the vehicle and its engine and equipment, and also of the principles which have governed its design. Formulæ and calculations are of secondary importance, as the repairer's work is the readjustment or renewal of parts which have gone out of order in service.

This book is designed for the student entering upon the subject for the first time, and is equally valuable for the owner-driver who wishes to take a close practical interest in his car or the transport manager whose duty it is to be familiar with the details of the fleet of vehicles under his supervision. Although it deals with current American practice, it is none the less useful in Great Britain on that account, as the main features of design are well standardized. The descriptions and explanations are given in terms which will present no difficulty to any class of reader; technicalities have been reduced to a minimum and fundamentals are stressed in the simplest possible manner.

In each section of the work, a sufficient outline of the fundamental theory is given, and special mention may be made of the way in which the electrical equipment is introduced by a statement of the theory of magnetism and electricity. Then follows the descriptive and explanatory text relating to the parts under discussion, and this generally terminates with a description of the mechanical troubles most likely to occur. In this way the student is led directly from theory and construction to the actual contacts, whether formal or informal, which he will make with the problems of maintenance and repair, and prepare him for the best use of the instruction handbook issued with each vehicle. J. A. C.

Bibliographia Primatologica

A Classified Bibliography of Primates other than Man. Part 1: Anatomy, Embryology and Quantitative Morphology; Physiology, Pharmacology and Psychobiology; Primate Phylogeny and Miscellanea. By Theodore C. Ruch. (Historical Library, Yale Medical Library, Publication No. 4.) Pp. xxvii+241. (Springfield, Ill., and Baltimore, Md.: Charles C. Thomas, 1941.) 8.50 dollars.

THE scope of Dr. Ruch's bibliography is fully indicated by its title. It makes available, both to laboratory workers and to others who are interested in the subject, a comprehensive list of published papers on the anatomy, physiology, pharmacology and psychobiology of monkeys and apes.

The anatomical section deals first with embryology and general morphology, and then with the various systems of the body. The physiological and pharmacological papers are also classified primarily according to the body systems, while the section on psychobiology is organized by broad subject headings. The further subdivision of the various sections is excellent, and it is a simple matter to find whether or not papers have been published on any aspect of the primates. There is considerable cross reference, and there is an index of authors which includes some two thousand names. A very large number of individual papers are cited. The abbreviation of journal titles is according to the World List of Scientific Periodicals.

Dr. Ruch deserves the warmest thanks of students of the primates for having successfully undertaken a most laborious and painstaking task. "Bibliographia Primatologica" represents both a great public-spirited achievement and a monument to what is already known about man's closest relatives in the animal world. His work will lighten the effort not only of research workers already engaged in this field of study, but also of recruits to the subject.

Thermionic Valve Circuits

By Dr. Emrys Williams. Pp. viii+174. (London Sir Isaac Pitman and Sons, Ltd., 1942.) 12*s*. 6*d*. net.

BASED upon the lecturing experience of the author, this book presents an outline of the theory of the operation and design of thermionic valve circuits in a form suitable for university students during the final year of their degree course in electrical engineering. The treatment is confined to a consideration of the principles of the use of valves in their various forms in radio transmitters and receivers, and no attempt is made to describe how the different functions are realized in practice. While it is assumed that the reader has a knowledge of alternating current theory and the associated mathematics, a short summary of the vector algebra required for this subject is given in the first chapter. Subsequent chapters deal with the valve, and its use as an amplifier, oscillator, detector, frequency changer and modulator. The treatment throughout the book is very clear and straightforward, and appears to be almost entirely free from errors or misprints.

While there are one or two places in which the descriptive matter might have been expanded, the author has probably been wise in keeping brevity before him as one of his main objectives. Certainly the modern, hard-pressed university student will appreciate this in a book which is admirably suited to his purpose.

The Cathode Ray Tube and its Applications

By G. Parr. Second edition. (First published under the title "The Low Voltage Cathode Ray Tube".) Pp. viii+180. (London: Chapman and Hall, Ltd., 1941.) 13*s*. 6*d*. net.

THIS book was first published in 1937 under the title "The Low Voltage Cathode Ray Tube", which was somewhat misleading in view of the fact that it deals with the various forms of cathode ray tube operating at accelerating potentials up to about 5,000 volts. The first three chapters deal with construction and operation of cathode ray tubes, their focusing arrangements and the interpretation of the patterns traced on the screen for various currents or voltages applied to the deflecting system. After two chapters devoted to time base circuit arrangements, the remaining chapters deal with the application of the tubes to various radio engineering, including television, and industrial uses. The book concludes with an appendix on photography and a most valuable classified bibliography of the subject.

The publishers are to be congratulated on the general production of this book, especially on making it much slimmer by the simple expedient of halving the thickness of the paper. The book should prove most useful to all those—and they are very many indeed just now—whose duties bring them very frequently into contact with cathode ray tubes.

PHYSICISTS AFTER THE WAR*

By SIR LAWRENCE BRAGG, O.B.E., F.R.S.
Cavendish Laboratory, Cambridge

WHILE scientific men of all kinds have been called upon to use their skill and knowledge for the nation's service in the present War, certain classes have been in especial demand, and the physicist is ranked among these 'scarcity categories'. The demand for physicists exceeds the supply, and universities have been pressed to train as many men as possible to fill the gap. There was no such general demand for the services of scientists in the War of 1914–18. Although there were some technical applications which called for trained scientific men, in the main that war was fought with comparatively simple gear. Physicists are now being used to develop and use all the lighter apparatus of war, the instruments for communication, for detection of aircraft and submarines, and for direction of our batteries. They are increasingly applying their analytical technique to operational research into the most effective way of using our weapons. Many of these latest developments are directed by men supplied by our industrial or university laboratories.

Physicists in general have been drawn into the service of the country in a way that has never happened before, and for the university scientist in particular this has meant a change of outlook and of occupation of a very revolutionary kind. In peacetime, the pure scientist, as contrasted with the applied scientist, works in a world of his own, not because he is an unpractical dreamer, as is often supposed, but for a very different reason. He is generally carrying out his particular task, the discovery of new knowledge, in an efficient and practical way, but although his researches may eventually have far-reaching consequences in altering the conditions of everyday life, he is cut off from these applications by a long interval of time. It is unusual for any great discovery in pure science to find an application in everyday use in less than thirty or forty years, since this time is required for the technical industrialist to see its possibilities and explore methods of using it for practical purposes. In the War, the pure scientist has to join the applied scientists and become a technician. He has to use his skill and knowledge to aid in devising gear which can be put to practical use in one or two years. A wider world has been opened up to men of science as the result of their being drawn into the War. They see more of the way the country is run. They are accused, with considerable justice, of being somewhat free in their criticism of many of the things they are seeing for the first time. Some of these criticisms are ill-founded, being due to a slowness in realizing that a country is a more complex entity to organize than a laboratory, but some are worth listening to, because they come from a body of men whose discoveries have been largely responsible for introducing the new technological era, which has completely altered the way we all live.

One thing has been clear. It has been of immense advantage to Great Britain in this struggle to have a reservoir of scientific researchers on which to draw. Their contributions cannot be described now, but when it is possible to do so, it will be found that our men of science have played no small part at more than one critical time. We are all hoping that we shall not drift back after the War, but will use our national assets of character and brains to make the country a better one than it has been during the last twenty years. I wish here to take stock of one particular part of these assets, our body of physicists, attempting to see what material we have got and make some suggestions as to how we could train and use it better.

My own experience has been gained in university work, and it is inevitable that this article should reflect the views thus engendered. I should be very sorry, however, if any part of it were taken to indicate a belief that the physicist who devotes himself to pure science has higher ideals or is more representative of his profession than his colleague who devotes his gifts to applied science. It is to our discredit as university men that we should sometimes be accused as a body of holding such views; it is evidence of a failure to take responsibility and enter into the life of the country. I hope, on the other hand, that it will be clear from what I have written that I am seeking to set our own house in order, to see how we can best equip the students committed to our care to take their part in applying their science for the benefit of all.

A Census of Physicists

It is interesting to assess the number of scientists, and of physicists in particular, in Great Britain. An estimate can be got in two different ways which roughly check each other. In the first place, we can find from the records of universities the rate at which scientists are being produced. The calculation is most straightforward in the case of the large modern universities. Each of these, such as Birmingham, Manchester, Leeds, or Liverpool, is the centre of a drainage area separated by watersheds. The students on the whole join that university to which they can travel backwards and forwards daily from their homes, and so one can calculate with some exactitude how many millions of the population each serves. From my experience at Manchester and as external examiner in other universities, I arrived at a rough estimate that one good physicist was bred per year per million inhabitants. By a good physicist I mean a man capable of independent thought, with a flair for his subject. For example, at Manchester, where we had excellent secondary schools seeking out and training all likely material, three or four such men a year was the average product drawn from a population of about four millions.

Again, we now have for the first time a census of the men of science in Great Britain; it is provided by the Central Register initiated by the Royal Society. The card index of the Central Register contains the names of all scientists in Great Britain, together with information about their scientific careers, experience and special interests. The term 'scientist' is not easy to define, but it has been taken to cover all who have received higher scientific education, have taken up a post in industry, Government service or the universities, and have continued to use their scientific knowledge for research or administration. The total number of scientists on the list at the beginning of the War was 12,000, of whom 1,200 were physicists. We may compare this with the above estimate that the population of Great Britain of 45 millions is producing one physicist per million per year; if one takes an average working life of thirty years, the two estimates agree. It is of course true that the relative numbers of scientists in different categories might be changed by a change in the importance and interest of the various branches, but it is doubtful if the grand total could be much increased. The net cast by the system of scholarships is so effective that most school students who show intellectual promise have the opportunity of higher education. One curious exception is to be noted, the very small proportion of scientists coming from the great public schools. Whether this is due to the direction of the brightest boys at these schools into other subjects, or to the fact that boys from the well-to-do homes which can afford a public school education are naturally drawn into other walks of life, I do not venture to judge; but it is an interesting fact, for example, that among the heads of physical laboratories in Great Britain, only one in a hundred received his education as a boarder at a public school. The secondary schools and grammar schools are the source from which the body of British scientists is almost entirely drawn.

---

* From a lecture at the Royal Institution, delivered on March 26.

Fundamental Research

How can we best use the physicists which Great Britain breeds, both for pure research and for the equally vitally important industrial research? To take in the first place the well-head from which the flow of scientific thought starts, the fundamental research divorced from all thought of its ultimate use or effect, we may claim that this is one of our great assets. Complacency is always disastrous, and I do not want to be understood as asserting that there are no improvements to be made in the system of combining such fundamental research with university teaching which has grown up in Great Britain. But with all its blemishes, this system has succeeded in keeping our science, and physics in particular, well in the forefront of the world's scientific endeavour, and this success is due to the existing structure.

I think this is worth stressing because ardent reform is in the air, particularly in the direction of a more conscious planning of the fields of research and their division between different centres, and of the foundation of institutions for pure research divorced from teaching. Proposals for the latter should, I think, be scrutinized very carefully. The great asset of university research is the constant flow of young men through the university, bringing their own original and fresh minds to bear on the lines of work of the school to which they come, and of the contacts between men engaged in widely different subjects. Some few men of science remain individualists all through their careers, working alone or with one or two assistants. Examples of physicists of this type must be in all our minds, and we recognize the great contributions they have made to our science. But the majority, after the first decade of their research careers, continue to live their scientific lives for the most part through their students. Battening upon students, using their freshness for selfish ends, is of course one of the major scientific crimes, and unhappy is the laboratory which has such a head, but there is a better and more normal side to the picture. The purest pleasure in scientific work is to see the germ of an idea one has planted in a younger man's mind develop in a way and to an extent one could not have achieved or foreseen oneself, and to see him get recognition for his work. I think too that teaching, if treated as the art of putting ideas in a simple and fascinating way, is one of the great safeguards against getting stale. There are many periods when research goes badly and is disappointing, and it is refreshing to have as a background the regular teaching routine, with the satisfaction it brings of a necessary and congenial task duly accomplished.

In contrast to the flow of keen young research students through a university, a central research institution has a comparatively static staff and there is considerable danger of fossilization. As would be expected, this tendency is much more noticeable in the later stages; it is scarcely likely to appear within the first decade of an institution's existence. It is less likely to occur when the central institution has a constant flow of men through it, who are given research grants and are attracted by the special facilities for work in their chosen line, for such a place is in effect a school for postgraduate study and has the same advantages as a university. Fossilization is seen at its worst in the laboratories where there is no such flow, where members of the research staff enter as young men and continue to do work of much the same character throughout their lives, and where advancement is rather by seniority than merit.

To sum up, it is doubtful, to say the least of it, whether the advancement of pure science is fostered by taking men from universities and setting them to work in central research institutions devoted to some special branch, however fine its buildings and equipment. The necessary stimulus appears somehow to be lost. A curious fatality attends such conscious planning of research. Large endowments given to special fields are apt to produce comparatively meagre results, which are completely outdistanced by some unplanned fundamental discovery appearing at first to have little bearing on the subject. Polanyi (Manchester School of Economic and Social Studies, Oct., 1938) has put this point very well in an article on the "Rights and Duties of Science". It will be objected that a central research institution can provide equipment and other facilities on a scale which may be impossible at a university, and I think that this valid objection points the way to the right solution. The strikingly successful places of this kind are those which may be regarded not as a body of men, but as a body of equipment. Such a place has a nucleus of permanent staff and accumulates traditions of technique peculiarly its own, but its main service is as a place open to all for short periods of intense work, and its main population a changing one.

Physics in Industry

Although we have good reason to be proud of the contributions made by Great Britain to fundamental scientific knowledge, we cannot feel satisfied that full advantage is taken of this asset in our industries. The educational system has a heavy responsibility to bear. In Bernard Shaw's "Major Barbara" the millionaire Undershaft is looking for a successor to whom he can hand over the control of his great armament firm, and deplores the difficulty of finding a boy of native genius who has not been spoilt: "if he shows the least ability, he is fastened on by schoolmasters; trained to win scholarships like a racehorse; crammed with second-hand ideas; dulled and disciplined in docility and what they call good taste; and lamed for life so that he is fit for nothing but teaching."

The bitter truth of this reproach must have struck many who have trained successive generations of honours students at a university. In former days many boys of the right type went straight into industry, and Great Britain's leading position was largely due to their inventive genius. Nowadays the majority get scholarships which enable them to go on to universities, and it is our responsibility to see that we give them the right training and send them back to industry to play their part. Two difficulties stand in the way. In the first place, the boy has lost something vital through the too close attention to his studies demanded by the need to win scholarships and pay his way. We cannot sell him to the industrialist when we have finished with him; he has not learnt to mix with other people and form one of a team, to take responsibility, to trust his own judgment and have initiative. Such qualities are learnt through games, hobbies, camps, running school activities and a host of other things which most boys get but from which the really clever boy is too often largely debarred by being recognized as a potential scholarship winner. In the second place, too many of our best students want safe jobs with immediate returns. The sacrifices they and their parents have made, and the work they have put into their learning, make them feel that their high honours degree should by itself be a qualification for a good post. They regard their training as a guarantee that they shall be put in a senior position, not as a preparation which should help them to show that they deserve one. When they go into industry and come in contact with men who have not had a university training, there is irritation on both sides. The industrialist compares them unfavourably with boys who have worked their way up and become men of the world; the university product cannot understand why the knowledge he has so painfully acquired does not entitle him to immediate recognition.

I have purposely painted the picture in the darkest colours, knowing well how many cases of success might be quoted in refutation, because I wish to consider the remedies. I think the long course through grammar or secondary school and university represents too unbroken a concentration on the acquisition of knowledge. I have on three occasions had the interesting experience of being a visiting professor for several months at various American universities. Although science students in Great Britain may be more advanced on the purely academic side than American youths of corresponding age (they can answer harder examination questions), it was my impression that the American student is more practical, handy, and bold at setting up apparatus. He gets this largely through his experience in the long summer vacation, it being a general practice to engage in some form of manual work. It is not so easy to organize similar activities for our students, though a certain number already are taken on for short periods by industrial firms. I think, even when this is done, that the periods are too short and come too late. The important time to make the break, it seems to me, is between school and university. If all our honours physics students had at least six months working for an apprentice's wage in some industrial concern, before they came to the university, I believe it would be of the greatest benefit not only to those who plan an industrial career later, but also to those who will become teachers of the next generation in due course and should have seen something of a wider world.

One suggested scheme for the future is therefore to copy our engineering confrères, and encourage physics students to put in a spell at works between school and university. Another suggestion is to follow the example of the medical schools. Though a large part of the teaching in a medical school is done by the permanent staff, an important part is that given by practising physicians and surgeons in the form of short specialized courses. Why not invite some of our leading technologists to do the same in our physics schools? As well as giving the students a valuable experience, it would give the industrial experts a place in our universities, a right to take part in their counsels and help to guide their policy.

Finally, there is the possibility of bringing back senior men in industry for short or long university courses specially arranged for them. Such courses can range from a conference devoted to intensive study of some special branch lasting for a few days or a week to a refresher scientific course extending over months. There is one conclusion to which I have come, as a result of being concerned in the organization of short courses of this kind, which applies to all types. The most successful examples are those where the university has concentrated on giving the industrialists a well-prepared summary of recent advances in pure or fundamental science, not those where it has attempted to go outside its own field and talk about "Physics in Industry". Let each man stick to his own job. Advances are so rapid, the literature is so voluminous, that a busy industrialist must find it difficult to keep abreast of the times. This is where his university colleagues ought to be able to help him, if they are worth their salt. They can sort the wheat from the chaff, tell him what new ideas are important and what are not, and provide him with a background of knowledge which he can use to solve the many problems of his particular industry. The industrial physicist on his side has something to which the university physicist cannot aspire, a wide and expert knowledge of the many problems of his industry and a sense of values as to what is important to it. It is for him to see how this new knowledge may aid him.

The same consideration applies in another way to research carried out in the universities at the behest of industry, and perhaps supported by it. Such arrangements forge the links closer, which we all desire, and can have highly important results. They must fit in, however, with the main function of university research, which is to increase the body of fundamental knowledge irrespective of its immediate application. This separation of function must be kept in mind. Any knowledge discovered at a university should be free to all, and the university scientist should not be forced to keep his knowledge in water-tight compartments, to remember what he may divulge and what he must regard as the peculiar property of a particular outside body which is financing a research in his laboratory. Freedom of discussion and exposure of his work to general criticism are the breath of life to the university worker.

Physicists in the Service of the State

The industrial research associations and laboratories partially or wholly supported by the nation, which have been started since the War of 1914–18, are in some respects in an intermediate position between the universities and industry. Their work is designed to help their particular industry, but they are also repositories of general knowledge and are in a position to undertake long-range research which will ultimately benefit the whole industry, as well as to apply themselves to particular problems of immediate interest.

With no disparagement of the achievements of these associations, and with full recognition that they represent a new experiment in organization of scientific endeavour, in planning for the future one cannot consider that the last word in defining their scope and function has been said. They have peculiar difficulties of their own. The university research worker is kept on the alert by the excitement of the chase. He is free to pursue any fascinating line which opens up, irrespective of its applications. He is hardened by the unsparing criticism of other experts if he makes mistakes of fact or logic, since his work is published and runs the gauntlet of free discussion. The industrial physicist is kept on the alert by the demands of his industry. What he is doing may affect the success or failure of a costly process, or lead to a new product for which a wide demand is anticipated. He runs the gauntlet of criticism by his colleagues in the works, and of the fierce test of results. The danger of the research association is that of its men working in a vacuum, where they miss both of these incentives.

I am emphasizing the difficulties of the research associations, not minimizing their achievements or suggesting that the experiment ought to be discontinued, a proposition to which I should be the fiercest of opponents. One ought, however, to face the existence of a widespread opinion that the flow from the research associations of Great Britain of fundamental ideas which would profoundly affect our industries has not yet reached the volume which had been hoped for and anticipated. Lip service is paid to research because it is respectable and fashionable to do so, but responsible industrialists in private express their disappointment. This is a challenge which must be met.

It seems to me that the difficulty partly arises from a wrong conception of the nature of research. To set aside a definite body of men, in a central institution, with orders to spend their whole time on research with some definite end in view, is to court disappointment. I come back to the idea of a central research association as being ideally a permanent laboratory with specialized equipment but with a changing population, not as being a permanent body of men.

While at Manchester I had an arrangement with certain firms which worked successfully. If one of their staff had a good idea, and the firm wished him to develop it without being subjected to the distractions of the works and its contacts, he was given a quiet laboratory at the University as temporary quarters. Should not the industrial research association be a place to which firms send suitable men from time to time, where equipment and assistants are available, and where they can for a year or more develop some good idea of the longer-range type? This plan has already been followed; I claim no originality for any of the ideas put forward here, but merely record those which I believe to be along the right lines. The opposite side of the picture is one which is only too commonly seen. A committee sits to direct a certain branch of research and a member proposes an investigation as worthy of attention. Staff and apparatus are set aside for it at the research association, and the men do their best to devise a technique and frame a programme. Through imperfect contact with industry, they drift off on work which may be excellent, but which is not really along lines of profound value. A committee is too impersonal a body to direct research, its members are generally too busy and important to give the necessary time and attention to detail.

When a new line of this kind is started in response to a demand by industry, it would be generally advantageous if at the same time an industrial sponsor were appointed, not necessarily a member of the committee, whose special responsibility it would be to visit the laboratory at short intervals and to spend quite a large part of his time in directing the effort. This is what in fact has happened in this War, and it is highly successful. Many extramural researches for the Services are being carried out in laboratories all over the country, and bodies like the Ministry of Supply appoint men from industry or from their own staff with precisely this function, who visit the research workers, who can be consulted freely, and who give just the required contact with what is actually needed. A day every other week of one expert's time is of infinitely more value than an hour or two of a large committee of well-known men which meets every two or three months. A similar plan widely carried out for industrial research would meet the need I have tried to express above; for the time being the sponsor drawn from industry would use the research association as his laboratory, to carry out his ideas, and there would be a constant flow of new people with new ideas through it.

Research and Administration

Some change in the methods by which Government scientific research is administered and financed appears to be very desirable. The Civil servant is, of course, right when he insists that everything should be done 'through the proper channels', and that attempts to short-circuit them lead to increased confusion and are essentially ineffective. There must be a recognized chain of authority by means of which action is taken. What we should ensure is that these channels are direct and open, not tortuous and clogged. It is here that sometimes one feels tempted to criticize the administration of research which is paid for by the Government, particularly research for the Fighting Services. An apparatus which is well designed for the administration and financial control of other classes of activity is inappropriate when it is applied to scientific research and development.

I believe the universities treat this problem in a better way. The ideal research unit is one of six to twelve scientific men and a few assistants, together with one or more first-class mechanics and a workshop in which the general run of apparatus can be constructed. I will add one further requisite: not only a good store of material but also of 'junk', old gear which has passed out of service but which provides a priceless source of oddments which can be used in constructing rapidly a first rough apparatus to try out some new idea. A famous man of science of a very practical turn of mind once told me that he regarded this junk as one of the most valuable assets of his laboratory; he was at the time feeling the pinch of moving into a tidy new building in which it had not yet had time to accumulate. Few who have an inspiration for a new piece of apparatus can visualize exactly how it will work to the extent of making a blue print of it. It grows by the close personal contact between researcher and mechanic, who should work side by side. It is not wasteful to duplicate lathes and other machines by giving each group its own workshop; the time of researchers is far more expensive than the overheads on machinery. With the same object in view, that of allowing the researcher to try out his ideas with as little delay as possible, the decision as to what particular piece of apparatus should be bought is best left to the researcher in all but major items. He should have an allowance for apparatus, to be spent at his discretion. The bills are passed through a central office, but the important thing is that the researcher should be free to get what he wants while in red-hot pursuit of the idea, and not have to wait to convince a central authority that it is necessary and order through it. This makes for true economy in the long run.

It may be objected that the freedom from control advocated here would be abused if it were granted. The point to be made in answer is, I think, that the check upon expenditure should be one of general review at the end of regular periods, not one of each detail.

Appointments

The working of the Central Register has been so interesting that one would like to see a permanent body with the same function set up after the War. We train our students for three or more years at the university, devoting much time and energy to their preparation for their careers. Do we pay an adequate amount of attention to directing them into the right careers when they leave us, a matter which is in every way as important as their training ?

Students are helped to find posts in two ways, either through the head of the department in which they have worked, or through a university appointments board. Outside bodies often apply to appropriate heads of departments when they have a post to fill, and consider they may have students of the right type, and much effective placing of square pegs in square holes is done in this way. However, I have always felt, as head of a department, that too much is left to chance by relying on applications of this kind.

A university appointments board has a better opportunity to survey the whole field both of posts and men, and many such boards do excellent work. They have their own particular difficulties, however. Too often the best men are placed by heads of departments or by their own efforts, without consultation with the appointments board, and the latter is saddled with the difficult task of finding posts for the less attractive candidates. This reacts unfairly on its reputation for supplying good men, and it also means that its wider knowledge of the field is of little use just where it should be most important, in the matching of the very best men with the best posts. An appointments board of the right kind should be the channel through which most appointments are normally arranged, not a last resort of the desperate.

I cannot help feeling that it would pay us handsomely to centralize the arranging of appointments of physicists after the War, much as it has been done during the War. Any central board which did this work for the whole of Great Britain would require an absolutely first-rate man at its head whom we could all trust, for he would have grave responsibilities, but the task is so important that it is a worthwhile one for such a man. I envisage the board as keeping a dossier of every physicist in the country, such as the Central Register now has in its records. The total crop of young physicists each year is two to three hundred, a comparatively small number to handle, and the total number in Great Britain is, say, ten times as great (any more precise estimate depends on the definition of a physicist). It should not be difficult to establish a central channel for advising men about suitable posts and helping the very best men to get the most important posts, as each year's contingent comes to be considered. I know that I, as head of a physics department, would feel much more confident that my students were taking up the right work if I had such a centre to consult. I would feel that it had a much wider knowledge of the possible careers than I could attain to by my own rather sporadic efforts, because all employing bodies would consult it when once its reputation was firmly established.

The implication of this suggestion will be realized. It is in effect a proposal to organize appointments boards by subjects rather than by universities, and would require careful planning before it could be made effective. The intimate personal knowledge of the student acquired by the department in which he has worked is fundamental to any scheme, but the War has taught us the value of having one centre for the whole country.

Summary

The foregoing appraisal of our assets and our problems may be summarized as follows. We breed the right kind of physicist, and the combination of pure research with teaching at our universities, together with the constant flow of young research students through university laboratories, is effective in producing fundamental advances in pure science of the highest quality. We are not so successful in using this asset in the field of applied physics, and some of the causes are analysed here and remedies suggested. The training of our physicists is literally too academic. This does not perhaps matter so much in the case of men taking up pure research, but it is a big handicap to the men going into industry. It is suggested that more of our physicists, now that their subject has made a recognized place for itself in industry, should have works experience as engineers do, and that the best time for the relatively shorter period they can afford to spend in works is between their school and university. An early experience of this kind would make it easier for the student to take his place in industry when he leaves the university.

We wish to ensure that the undoubted inventive genius and scientific ability of the students we train is used by industry to the best advantage. Striking successes have been achieved by industrial organizations which are large enough to have research laboratories of their own. The close contact with the works provides the inspiration and sense of practical values which are essential for fundamental and original ideas profoundly affecting the industry. Research associations represent an attempt to advance the standard of technical achievement for groups of firms, many of which cannot afford laboratories of their own. Although such associations have scored many successes, they have been successes of tactics rather than of strategy ; the conditions under which they work make it difficult for them to produce the really fundamental ideas. It has often been stressed that a primary requisite for their success is that the firms which support them should be willing to pool their knowledge and consent to problems which they know to be really important being handed over to a central organization ; no scheme can hope to work unless this is done. If such a pooling is carried out by general agreement, it would be possible to alter the character of a central research organization. At present its greatest danger is that of becoming a static body of researchers cut off from the real needs of industry. It should be able to become a common research centre with a continuous flow of men through it, providing a laboratory where any man with a good idea could come to work it out, and a source of men going back into industry with a wider knowledge of all its problems. It is only under such conditions that really fundamental advances can be made.

THE EYE IN INDUSTRY

CURRENT interest in the health of industrial workers and in the maintenance of a high level of output made the conference on the "Eye in Industry", held under the auspices of the London Branch of the Institute of Physics on June 20, very opportune. During the first half of the proceedings six papers were given on different aspects of the subject, followed, after tea, by a lively discussion, in which many of the audience took part. The success of the meeting was enhanced by the kindly hospitality enjoyed at the South-West Essex Technical College, where the conference was held.

In the opening paper, Dr. W. D. Wright gave three reasons for a discussion on the eye in industry as opposed to the eye in other spheres of human activity. There is in the first place the special nature of many of the tasks that have to be undertaken and that are peculiar to industry, tasks, moreover, that have to be repeated and continued for many hours at a stretch. Secondly, there is the question of responsibility, either on the part of the employer or possibly of some Government department, for the health of the workers. In the home, the individual should, so far as his means permit, make his own arrangements for good lighting and avoidance of eyestrain, but in the factory the onus rests on the employer. Any discussion should therefore aim at stirring the interest and the conscience of the employer, providing him with the data that he may properly demand and informing him of the facilities already available for the adequate solution of visual problems. There is thirdly the question of output and efficiency, matters closely related to good seeing.

Hence, although the eye responds in the factory in much the same way as it responds elsewhere, yet there are excellent reasons for paying special attention to its performance under industrial conditions. The importance of the eye, as distinct from the other sense organs, lies, of course, in the fact that a very large fraction of our knowledge of the external world is derived visually. Nearly all the information which we have of our immediate surroundings and of the events taking place in the vicinity is obtained from the very variegated pattern of light, shade and colour which is focused by the lens system of the eye on to the light-sensitive retina. Shape, size, texture, distance and movement of an object are all observed and recorded because of the existence of contrasts between the object and its background and between different markings on its surface, as in the grain in a piece of wood, so that good seeing demands good contrast perception. Attention has to be paid to the image-forming part of the visual system, as this may be defective and require correction with spectacles, and also to the performance of the light-sensitive mosaic on the retina, which can detect small contrasts and resolve finer detail when the level of illumination is raised. Eyestrain occurs when the muscles controlling the convergence of the two eyes on to the object under examination and those governing the focusing of the lens system have to operate under conditions of poor visibility and distracting lighting. It is the job of the employer to provide conditions that achieve the best possible compromise between the requirements of his technical processes and the maintenance of maximum visual efficiency.

Mr. E. W. H. Selwyn illustrated this compromise by reference to the peculiar problems that arise in the photographic industry in connexion with the illumination of dark rooms. Sufficient light has to be provided to conduct the various photographic processes, but not so much as to fog the emulsion. In choosing the colour of the light to be used, a balance has to be struck between the parts of the spectrum to which the photographic emulsion is least sensitive and the eye most sensitive, taking into account the changing spectral sensitivity of the retina in dim illumination. It follows that the most efficient colour of the illumination will vary with the type of emulsion: orange for ordinary emulsions, red for the orthochromatic type, and green for the panchromatic and infra-red forms. In all cases the level of illumination is low, leading to poor visual acuity and contrast perception. As a consequence, objects such as dark room clocks must be large, and white markings should be provided to assist in getting about the dark room—aids reminiscent of the black-out.

Another interesting aspect of the problem is concerned with the time required to become adapted to the dark room illumination. In rooms illuminated by red light, vision, even when fully adapted, is mediated largely through the cone mechanism in the retina and the cones acquire their maximum sensitivity after only a few minutes. In the rooms illuminated by green light, on the other hand, the rods will operate, and as these take at least thirty minutes to acquire their maximum sensitivity, there is a marked difference in the adaptation times for the two forms of lighting. Mr. Selwyn also reported his experience that when working in a dark room he found that he required the aid of negative lenses with a power of -2 dioptres in order to focus distant objects clearly. This he attributed to the spherical aberration in the lens system of the eye, since at low intensities the iris is expanded and the marginal zones of the system come into action. There was some difference of opinion on this matter during the discussion, both as to magnitude of the effect and its cause. It would appear that some observers have not been conscious of the need for negative lenses; indeed, one speaker maintained that positive lenses were required, yet it is not a matter that should be lightly dismissed without further investigation.

The part played by light in aiding the performance of the eye was dealt with by Mr. W. R. Stevens. He stated the basic principles of good lighting, including adequate illumination, reasonable uniformity, freedom from glare and the provision of the proper contrast between the object and its surround. He urged the greater use of colour, both as a means of improving contrasts and in brightening our workshops; in Great Britain we tend to be conservative in our devotion to greys and other dull colours for the decoration of machinery, with the notable exception of the gaily coloured agricultural machines. An important advance in the last few years has been the introduction of the fluorescent tube as a light source; its extended area and low brightness result in a reduction of hard shadows and the absence of glare, while through the choice of the fluorescent material, the colour can be controlled very successfully. A good approximation to daylight can be obtained, and, through the employment of daylight fluorescent lamps, the illuminating engineer can mix artificial light with daylight without introducing the disturbing æsthetic appearance noticeable when ordinary tungsten lamps are used in a room which is simultaneously being illuminated by daylight.

Questions were asked about the extent to which the design of lighting installations should attempt to simulate daylight, both in its colour and distribution; the evidence goes to show that generally we prefer the lighting to which we have been accustomed, so that any tendency towards one particular form of installation has no justification from experience. The design of windows and daylighting is largely an architectural problem, and for illuminating engineers to arrange their lighting fixtures to give an imitation of window lighting would impose an unnecessary, artificial restriction on the freedom they otherwise possess.

Mr. G. H. Giles, who spoke from the point of view of the optician, claimed that the optician is in a position to act as a clearing station for the specialist—the physicist, the illuminating engineer, the medical practitioner. There is a very obvious need for close attention to refractive errors among the workers in industry, since statistics, many from the United States, show that the percentage of workers with visual defects is very high. Correction of the defects with spectacles leads to roughly 20 or 30 per cent increased production, with a corresponding decrease in the discomfort and fatigue of the worker. Naturally, there is a greater tolerance for defects in one type of work than in another, but there are occupations where visual aids are desirable, even though the vision of the worker is normal. Thus, where prolonged close work is involved, it has been found that much of the strain can be removed if the worker wears a pair of glasses which combine a lens and prism for each eye. In this way most of the need for excessive focusing and excessive convergence of the two eyes can be avoided, with a consequent lessening of the muscular effort; Weston and Adams have shown that great benefits have resulted from the use of such aids, leading to a marked reduction in fatigue and eyestrain, and a significant increase in output. During the discussion, the value of spectacles of this type was especially emphasized in the case of prolonged near work and it was considered that they could be employed on a far wider scale than is the case at present.

Tests for eye defects other than refractive errors, such as colour blindness and defective night vision, may also be needed. Recently, a number of workers at a factory claimed to have poor night vision, but when tests proved them to be normal, it transpired that they had hoped in this way to avoid fire-watching duties! Opticians also deal with protective glasses against damage from different radiations and from other hazards such as flying chips and molten substances. Finally, Mr. Giles referred to a scheme inaugurated by the Joint Council of Qualified Opticians for testing the vision of factory workers, whereby a rota of opticians is made available for the purpose. A valuable service was being performed in this way before the War, but during the War the scheme has proved even more useful and has been officially adopted for Royal Ordnance Factories.

The routine eye examination carried out by opticians under the scheme of the Joint Council of Qualified Opticians was described in some detail by Mr. R. A. Rider. As the testing of each patient may occupy at least thirty minutes, the time required to deal with a works in which, say, 20,000 persons are employed is very great. The tests may therefore have to be directed in the first place to those who show symptoms of ocular defect.

In the final paper Dr. H. Lowery broached a rather different aspect of the subject when he referred to the part played by the eye during training for such activities as carpentry, metal work and other technical handicrafts. This is very much a question of securing proper co-ordination between hand and eye and it is important, especially at the present time, to know why and how training improves the visual processes. Before the War of 1914–18 it was customary in schools to give special classes for what was called "eye training", but since then the method has been discarded. It is undoubtedly in part a psychological problem, as are, in fact, all visual problems, and training undoubtedly induces alertness in making particular types of observation. In the discussion, for example, reference was made to the very high accuracy to which a trained workman could judge angles and other dimensions of an object. Another point was made that, in problems of discrimination and visual estimation, the boundary line between physiology and psychology is rather vague, so that the possibility that training may modify the response of the eye as well as the reaction in the brain ought not to be overlooked.

There is obviously a great deal still to be learnt about how the eye works and how to apply the information that is available. The problem is a vast and intricate one and the conference served to bring different interests together to form a pool of knowledge, knowledge that has somehow to be passed on to the whole industrial community.

CANCER RESEARCH IN GREAT BRITAIN

THE eighteenth annual report of the Grand Council of the British Empire Cancer Campaign (11 Grosvenor Crescent, London) was issued in February. At the meeting at which the report was presented, it was stated that more cancer research had been carried on during the War than had been anticipated in 1939. The summary refers with justifiable pride to "the lead in cancer research which Britain is still giving to the whole world". On account of this, appeals for financial assistance for the Campaign which had been discontinued at the beginning of the War will be made again.

The report itself has its familiar form, and shows that a considerable amount of work has been carried out in Great Britain, though there is little research to report from the Dominions. During the year which ended last summer the campaign expended almost £45,000 in supporting research workers and institutions.

Advances in our knowledge of cancer have been made in many countries. Important contributions have been made in the United States to our understanding of the nature of filterable tumours and the inheritance of cancer in mice. Japanese workers have made important discoveries on the experimental induction of liver tumours. But "the study of cancer-producing and cancer-inhibiting substances is predominantly a British study". Perhaps the most interesting carcinogenic agents are those which occur in living organs. The first descriptions of such substances came from Russian workers. Examination of bile and liver tissues has been carried on in Great Britain, and tumours have been produced in mice by injection of extracts of human livers.

The testing of more than seventy compounds related to known carcinogenic compounds during the last three years at the Royal Cancer Hospital has shown that the capacity to produce skin tumours by painting does not always run parallel with the capacity to produce sarcomata by subcutaneous injection.

Progress has been made in the study of the metabolism and excretion of carcinogenic hydrocarbons. The fluorescence of these compounds makes it easy to follow their excretion. At the Royal Cancer Hospital it was shown that when 1 : 2 : 5 : 6 dibenzanthracene is fed to rabbits it is excreted in the urine as a dihydroxy derivative, and later American work has confirmed and extended this finding. Prof. F. Weigert and Dr. J. C. Mottram have shown that the fluorescence of benzpyrene varies from blue to violet in animals injected or painted with the compound. The blue fluorescence is seen in the bile of treated animals. At the Glasgow Royal Cancer Hospital, work on the metabolism of benzpyrene indicates that a hydroxy benzpyrene is excreted in the bile of animals injected with the hydrocarbon.

Workers at Leeds have produced tumours of the bladder in dogs after very prolonged dosage of pure β-naphthylamine by mouth. This confirms the earlier work of Hueper in the United States, and indicates that β-naphthylamine itself is probably the primary cause of cancer of the bladder in dye workers. Careful research carried out in Newcastle-on-Tyne has shown that wood smoke such as is used for smoking food is not carcinogenic to animals.

Most carcinogenic compounds inhibit the growth of normal and malignant tissues, and the correlation between carcinogenicity and growth-inhibiting power has been thoroughly investigated at the Royal Cancer Hospital. Two compounds—1 : 2′ azonaphthalene and 1 : 2′ diamino 2 : 1′ dinaphthyl—have been found to be inhibitory but noncarcinogenic. It is suggested that some compounds of this type might be tested clinically for treatment of cancer.

Animal tumours can be grown in tissue culture and often, on retransplanting into animals, lead to development of tumours. A mouse tumour grown *in vitro* in this way in Birmingham for more than eight months was able to produce tumours in mice and then lost this power of growing *in vivo*. In Glasgow a fowl tumour grown in tissue culture did not always produce tumours when inoculated into fowls. There is evidence that tumours while still growing in tissue culture may lose their ability to grow in animals.

Photomicrography of irradiated malignant tissues, using monochromatic ultra-violet light, shows the position and amount of nucleic acid material in cells. In eleven out of fifteen cases examined, a striking increase in nucleic acid in the cells occurred after irradiation. The increase in nucleotide material is not confined to malignant cells, but has also been observed in normal and hyperplastic tissues.

In spite of difficulties due to the War, progress in technique of therapy by radiological methods continues. At the Mount Vernon Hospital it has been shown that treatment of carcinoma of the vulva with a given dose (1,200 r.) is much more effective if given at high intensity (350 r. per minute) than if given at low intensity (20 r. per minute).

At St. Bartholomew's Hospital more experience has been gained in the clinical application of the million volt X-ray apparatus. An increasing number of patients is being treated and the results obtained suggest that it is particularly effective in treatment of cancer of the rectum, a site in which treatment by softer X-rays has not hitherto yielded satisfactory results.

Mr. E. N. Willmer in Cambridge has examined the effect of trypsin on cultures of chick heart fibroblasts. A 1 per cent solution of the enzyme had only slight toxic effects but caused the cells to round off. A more dilute (0·1 per cent) solution caused the constituent cells of embryo chick heart tissue to fall apart. The separated cells were able to grow and form new colonies of cells.

Dr. A. W. Greenwood has continued to supply chicks and fowls to research workers investigating the pathology of fowl tumours. Careful observation and breeding of Brown Leghorn chickens has shown that there is considerable variation in susceptibility of this stock to the Rous No. 1 sarcoma. The inheritance of variation in susceptibility is being studied. The susceptibility in any one bird is not necessarily extended to all tumours. Thus a transplantable chemically induced tumour grows in birds from a strain resistant to the Rous No. 1 tumour agent.

Variation in reaction to the Rous tumour virus has also been encountered at the Middlesex Hospital, where the birds of a Light Sussex - Plymouth Rock cross could not be immunized, while Brown Leghorn fowls readily develop immunity to concentrates of Rous sarcoma. The low resistance of the Light Sussex cross-bred fowls may be connected with the capacity to yield chemically induced filterable tumours which have occurred in these fowls at the Middlesex Hospital laboratories. The serum of susceptible fowls may be able to agglutinate the Rous virus without neutralizing it, while the serum of resistant fowls may contain neutralizing antibodies without agglutinins.

Many efforts have been made to demonstrate a virus in 'non-filterable' tumours. At the Glasgow Royal Cancer Hospital filterable and non-filterable tumours have been compared by inoculation of tumour material which has been ground with and without sand. Filterable tumours are still transmissible after grinding with sand, but the infectivity of other tumours is destroyed by such treatment. Filterable tumours transmitted with ground tissue "grow in a diffuse manner with ill-defined edges, so that the muscle substance is deeply infiltrated over a wide zone". The non-filterable tumours grow from multiple foci, suggesting that they have developed from isolated cells or cell clumps; such tumours depend for their transmission on the inoculation of a sufficient number of viable cells. Work in the field laboratory at Sheffield indicates that the simultaneous injection of mouse tumour tissue treated with glycerol does not influence the incidence of tumours induced in mice by the injection of methyl cholanthrene.

The Clinical Cancer Research Committee of the Campaign presents a report in which material collected in 1938 and 1939, particularly with regard to uterine cancer, is considered in detail.

The body of work which is reported indicates that the impetus of cancer research in Great Britain even in war-time is considerable, and that with a return to peace-time conditions extremely rapid progress should be made.

E. Boyland.

ECONOMIC VALUE OF THE COMMON STINGING NETTLE

By DR. C. R. METCALFE
Royal Botanic Gardens, Kew

It is a well-known fact that the common nettle (*Urtica dioica*) yields a very strong bast fibre which was used in Great Britain until about 1860 for the manufacture of cloth. Since then its use has been discontinued because other cheaper, imported materials became available. In the past, nettles have been cultivated also in France and other parts of Europe for the production of fibre.

During the War of 1914–18, the Germans were quick to recognize the value of the nettle as a source of fibre. According to published information, 10,000 tons of wild nettles were estimated to be available in Germany. The collection of these was undertaken largely by children; transport being arranged in collaboration with the military authorities. The whole organization was controlled by the "Nesselfaserverwertungs-Gesellschaft" and the "Nesselanbau-Gesellschaft" which operated from Berlin, while the "Bayerische Nesselfaser-Gesellschaft" had offices at Munich. The estimated yield was between 1,500 and 2,000 tons of fibre, valued at between two and three million marks. This was to be used chiefly in the manufacture of textiles. At the same time, 3,000 tons of food from the leaves and 3,000 tons of by-product material suitable for use in paper and chemical factories were to be extracted. Other extracts included lignin, chlorophyll and potassium nitrate, while nettle products were even used in the manufacture of gas mantles[1].

At the outbreak of the present War, the German Government immediately appealed to the general public to collect nettles once again[2]. Apparently the nettles are still being used with success, for it was reported from Stockholm in the *Daily Express* on June 8, 1942, that about 5,000 railway carriage loads of stinging nettles will be collected in Hungary this summer for use as raw material for textiles.

Although most of these facts have been known in Great Britain for many years, it is only recently that it has been possible to arouse any interest in nettle fibre in commercial circles. The availability of more familiar fibres, and other causes, have closed our eyes to the possibility of making use of a very common and troublesome weed. About two years ago, however, samples of nettle bast fibre were extracted at the Royal Botanic Gardens, Kew, and sent to another institution for certain experiments which were then in progress. Tests, which were then made, fully confirmed that the bast fibre is remarkably strong and that it consists of a very pure form of cellulose. Other tests on fibre extracted at Kew were also made at the Imperial Institute, where it was demonstrated that good-quality paper can be made from the bast fibre. Larger samples of nettle fibre were prepared in 1941, which were examined by paper-making firms in Scotland, and pronounced to be very satisfactory. From the *World's Paper Trade Review* of May 15, 1942, it is learned that a Renfrewshire firm of paper-makers is prepared to purchase 1,000 tons of nettles this summer at a minimum price of £10 per ton, and that another firm in Fife is willing to buy 200 tons for experimental purposes. In the same journal it is also stated that steps have been taken to cultivate several acres of nettles for the same purpose, care being taken to do this only on land which is unsuitable for other crops.

It must be emphasized that the samples extracted at Kew consisted only of the bast fibre; the wood fibre, which possesses quite different properties, was a waste product. Unfortunately, it is difficult to reduce the wood fibre to pulp, so that this material cannot be used unless new and less expensive methods of treating it can be devised. The bast fibre represents only about 8–10 per cent of the dry weight of the nettle stem, so it can be seen at once that a considerable amount of material is likely to be wasted unless methods of preparation can be improved, or an alternative use found for the by-products. It is also important to emphasize that the quantity of available nettles is never likely to be sufficient to satisfy more than a small fraction of the paper requirements of Great Britain. The most promising line, therefore, would appear to be to make good-quality paper for special purposes. Whether it would be economically possible in Great Britain to use nettle fibre for textiles as in Germany needs further investigation.

It is not generally known that differences in the standard of living in Great Britain and Central Europe respectively made it economically possible to import dried stinging nettles from the Continent before the War. This material was used for the extraction of chlorophyll, which is employed to give a green colour to soap and other toilet preparations and, to a limited extent, in medicine. Nettles are more favourable than other plants as raw material for this purpose owing to the ease with which the chlorophyll may be extracted, as well as to the desirable shade of green which it exhibits. A great deal of the chlorophyll used in Great Britain before the War was imported ready-made from the Continent. It will be interesting to see whether, after the War, economic conditions will be such as to enable or make it desirable for us to import this material again.

There is, meanwhile, an admirable opportunity to extract chlorophyll for export to those countries which, like ourselves, were previously supplied from the European Continent. The desirability of effective collaboration between those who cultivate nettles for fibre and those who wish to use the leaf for the extraction of chlorophyll is clear for all to see. We might also emulate the German skill in using *Ersatz* material by devoting any excess of leaves to the feeding of cattle, even if the well-known value of young nettles as human food fails to command much popular respect. It is interesting to note in this connexion that the protein content of the nettle is high.

OBITUARIES

Prof. G. A. Reisner

THE death on June 6 last of George Andrew Reisner, professor of Egyptology at Harvard University, has removed from our midst one of the greatest and most successful excavators Egypt has ever known. His rival for the foremost place could indeed only be Sir William Flinders Petrie, his senior by some ten years, who is happily still with us. To assess the comparative merits of these two would be invidious, but a few sentences may perhaps attempt to sum up the special merits of each. Petrie has been essentially the pioneer. Before him, excavation was but a haphazard affair; no attention paid to detail, often in fact left to untrained native foremen. Petrie's field-work, starting full fifteen years before that of his American colleague, was the first to inaugurate careful planning of sites, with complete recording of pottery and smaller objects; and the prompt annual publication of results has been the greatest boon to our science. It cannot be gainsaid that Reisner greatly improved upon Petrie's methods. Never has there been such meticulous regard to the smallest objects, photography applied at every stage, the most careful training and organization of the workpeople, voluminous notes compiled with unremitting patience; and scholarly philological training at the back of it all. Alas, the inevitable consequence of such minuteness has been that publication has often been unduly deferred. Reisner's books are fairly numerous, always bulky, but their content covers only a fraction of the work that he achieved. It is devoutly to be hoped that those into whose hands his material now passes will repair the miscalculation here deplored. Thus only shall we be enabled to measure the full stature of the man, and derive complete profit from the astonishing achievements of his career.

From early work on cuneiform tablets, for which he received his training in Berlin, Reisner soon switched over to Egyptian studies, and in 1899 took charge of the Hearst Egyptian expedition to Upper Egypt. Here he unearthed important cemeteries of the early periods, especially at Naga ed-Dêr, near Girgah. In 1905 began the excavations on behalf of Harvard University which were continued down to his death, interrupted only by the three years spent in charge of the Egyptian Government Survey in Nubia (1907–9). Investigations in various Nubian cemeteries led on to excavations much farther south, when the tombs of many late Ethopian kings were discovered, and a most interesting settlement of Middle Kingdom date explored at Kerma. Two seasons at Samaria (1909–10) brought to light the palaces of Omri and Ahab, with many important remains.

But it was in the neighbourhood of the Pyramids of Gîzah that Reisner scored his greatest successes. The laying bare of the temple of the Third Pyramid resulted in the discovery of marvellous statuary, chief among which was the great slate group now in Boston of King Mycerinus and his mother. Even more valuable were the results of the excavations around the Great Pyramid. Here the symmetrically laid-out necropolis city of the nobles and princes of the time of Cheops was systematically investigated, the crowning find being that of the secret burying-place of that Pharaoh's mother, Queen Hetepheres. The chaste sobriety of the magnificent furniture found in this untouched burial forms a remarkable contrast to the far richer, but sometimes garish, treasures from the Theban tomb of Tutankhamūn, the most sensationa archæological discovery ever made.

This inadequate account cannot conclude without a brief impression of the man himself. He was an American of the Americans. With his powerful figure and forthright utterance he reminded one of Theodore Roosevelt, but hand in hand with these somewhat awe-inspiring characteristics went a kindness and hospitality unforgettable for those who, like the present writer, often benefited by them.

ALAN H. GARDINER.

Mr. C. C. A. Monro

CHARLES CARMICHAEL ARTHUR MONRO, who died on June 21, came of a Scottish family, that has had many distinguished members. It included three generations of professors of anatomy at the University of Edinburgh, all bearing the name of Alexander Monro, the second of whom (1733–1817) has given his name to the "foramina of Monro", which connect certain ventricles of the vertebrate brain. His great-grandson, David Binning Monro (1836–1905), was provost of Oriel College, Oxford, and a well-known Homeric scholar. Charles Monro was born in India on September 14, 1894, the younger son of the late Alexander Monro, who was director of public instruction, Central Provinces, and whose elder son, Alexander Monro, has also had a distinguished career in the Indian Civil Service. An uncle, the late General Sir Charles Monro, was commander-in-chief at the Dardanelles in 1915, and afterwards Governor and commander-in-chief of Gibraltar.

Monro was educated at Charterhouse, Eton (where he was a King's scholar) and Trinity College, Oxford. Going up to Oxford in 1913, he took Pass Moderations in Classics in 1914, and began to read for the Honour School of Lit. Hum. His studies were, however interrupted by the outbreak of war. He served in France and Belgium, and was wounded and suffered shell-shock in 1916. Returning to Oxford in 1920, Monro, who had become interested in zoology, decided to read for the Honour School of Natural Science in that subject, and did so until 1922.

After brief experiments in business and agricultural practice, Monro was appointed in November 1922 to an assistant keepership in the Department of Zoology, British Museum (Natural History), and was placed in charge of the collections of Annelids and Echinoderms. While doing a good deal of curatorial work on these collections, and being responsible for their removal from the Old to the New Spirit Building of the Museum in 1924, he devoted his attention mainly to the Annelids, and in particular to the Polychæte worms. In the course of the years 1924–39 he published some thirty-seven systematic memoirs, many of which were important contributions to the subject. They included, besides smaller papers, extensive reports on the large collections obtained by the *Discovery*, Great Barrier Reef, John Murray and B.A.N.Z. Antarctic Research Expeditions, as well as reports on collections made by smaller expeditions (*St. George*, *Rosaura*, etc.). There can be no doubt that Monro was well on the way to become a leading authority on the Polychæta. An interesting investigation of his was that on a species of Serpulid new to British waters, which he named *Hydroides incrustans*. This was found forming extensive incrustations in an enclosed harbour canal in Sussex where, owing to the discharge of hot sea-water from a power-station, the temperature of the water was many degrees higher than in the adjacent part of the English Channel. Monro felt some uncertainty whether the worms represented a species accidentally introduced on the bottom of a ship from a warmer climate, or whether the high temperature of the water had produced a neotenic race of a widely distributed species, *Hydroides norvegica*, showing well-marked differences in size and structural details from the typical form.

In one of his shorter papers Monro discussed the need for a re-classification of the Echiuroidea, and made some important proposals for the rearrangement and redefinition of the families and genera of that group. He was responsible for the reorganization of the starfish gallery of the Museum in 1928, and also rearranged the study collection of echinoderms in accordance with modern classification. Almost the whole of the "General Guide to the Exhibition Galleries", published by the Museum in 1931, was written by him. He edited, for publication by the Museum, a series of postcards dealing with the old herbal "Hortus Sanitatis", a task in which his considerable knowledge of medieval Latin proved of great value. One of his last official duties at the Museum was the preparation, jointly with the present writer, of a new "Collectors' Handbook" dealing with the collection and preservation of invertebrates other than insects. He wrote the section on Vermes in the "Standard Natural History" (1931), and articles on several groups of annelid worms in the Encyclopædia Britannica (14th edition). For about two years (1925–27) he was editor of the *Museums Journal.*

Soon after the outbreak of war, Monro's services were lent to the Ministry of Food, where he worked until his last illness. He had been seriously ill in 1935, and had undergone a severe operation. From that illness he had never completely recovered, and a second operation was performed a few weeks before his death. He possessed great charm of personality and a very open and upright character. He was a pleasant colleague and a good-natured companion, with a strong sense of humour and an acute and well-informed mind. Somewhat of a rebel, from his school days, against convention and what he considered social injustice, he was also interested in many aspects of learning and the arts, and was a man of very considerable culture and wide reading. He had a great love and understanding of poetry, and was deeply interested in theology and metaphysical philosophy. He always took a great delight in intellectual discussion, and many, no doubt, will remember a lecture delivered by him at a summer school at Cambridge in 1939 on the relation between science and religion. It seems to have been a desire to understand the deeper mysteries and problems of life that urged him to the study of biological science, and the same desire that led him, when already in his thirties, to embrace Catholicism, to which he was a fervent convert. He was keenly interested in the Neo-scholastic philosophy and in foreign politics, and was for a time honorary secretary of the Catholic Council for International Relations.

Until his health became seriously impaired, Monro had unbounded vitality and love of life, and of the good things it had to offer. His recreations included walking, swimming, yachting, fishing, shooting and fencing. For some years he was a leading exponent of the épée, being once runner-up in the British championship and one of the British representatives in a European tournament at Le Touquet. But above all he loved the open country and the hills, and most of his holidays were spent in walking in the Lake District, in Wales or in the west of Ireland. As a boy he had spent a number of holidays in France, acquiring a fluent knowledge of the French language, and an affection for the country and its people which he never lost.

Monro was twice married; first, in 1917, to Pamela Gartside Tipping, by whom he had one son (a captain in the Gordon Highlanders, missing at Singapore), and secondly, in 1927, to Sheila Mary Anderson, who, with their two young sons, survives him. H. A. BAYLIS.

DURING an acquaintance with Monro extending over some twenty years I have had, in common with many other zoologists, occasion to regard him with much gratitude, admiration and affection. In an era when good systematists are becoming lamentably scarce, Monro stood out as an example of the ideal systematic worker. His systematic knowledge of the Polychæta, in the first place, was wide, accurate and of an intelligent type, and coupled with the mass of detail at his finger-tips connected with the literature of the subject and the diagnostic features of the species contained in the group was a particularly useful acquaintance with their distribution and geographical relations.

Although dealing almost entirely with preserved material himself, Monro was always keenly interested in receiving news of the living animals and actively aware of the importance of their ecological relations. He was always thoroughly willing to assist ecologists by determining their material, and did it promptly and in the most helpful way. My personal gratitude to him was elicited by the assistance which he gave me in ecological work carried out during the Barrier Reef Expedition and during ten years of marine studies in South Africa. Among a group of systematists whose kind services made it possible to work out the results of these studies at all, Monro was outstanding as one of the most actively helpful: in fact, he was a member of that rather small class, the 'perfect systematists'. This was the more so because, as so many of his friends are aware, Monro was a personality of great liveliness apart from his official work altogether. Very widely read and capable of talking entertainingly and yet with balance on almost any subject, and possessed of abilities quite distinct from those required for his museum work, he was a very fully developed human being and a most welcome companion. T. A. STEPHENSON.

Prof. Joseph Paczoski

JOSEPH PACZOSKI, professor of the University of Poznan (Poland), who died on February 14, was a distinguished taxonomist and the founder of a new branch of botany, phytosociology. We do not know all the details concerning the last period of his life under German occupation in Poland; one can imagine, however, how much he must have suffered. At the beginning of the War in Poland, immediately after Poznan had been occupied by German troops, nearly all the university professors were arrested there, they were deprived of all their personal possessions, deported to the so-called General-Gouvernement and left to starve. This was also the fate of the 77-year-old Prof. Paczoski.

Joseph Paczoski was born on December 8, 1864, in Bialogrodka (Wolhynia). He was educated at the Agricultural School in Human (Ukraine) and afterwards studied and was assistant under the well-known Prof. Schmalhausen at the University of Kief (1888–94). He then held successively various posts. He was custodian of the Botanical Garden of St. Petersburg (1894–95), assistant at the Agricultural College of Dublany near Lwów (south-eastern Poland) (1895–97), director of the Natural History Museum at Cherson (Ukraine) (1907–20), founded by himself, director of the Steppes Preservation of Ascania Nova (1922–23). After the outbreak of revolution in Russia, Paczoski refused the very good facilities for scientific work offered him by the Soviet Government and left Russia for Poland. There he was appointed director of the National Park in Bialowieza (1923–28) consisting of primeval forest. At the same time he was professor of taxonomy and plant-geography at the University of Poznan. During about fifty strenuous years he published more than two hundred scientific papers and articles. These works have earned him a place among the best-known men of science in Europe.

When engaged in the study of the flora and of plant-geography he spent most of his time on excursions to many places ranging from the Baltic to the Adriatic Sea and eastwards to the Volga.

No other Polish botanist, and only a few from other countries, have succeeded in investigating such wide areas as Prof. Paczoski. He was considered to be the most outstanding investigator of the flora of south-eastern Europe. Prof. Paczoski was the originator of a new branch of botany, phytosociology. Until a few years ago men of science of western Europe had to refer in phytosociology to the treatise by M. R. Harper, "The New Science of Plant Sociology" (1917). Still more recently Russian botanists with their tremendous enthusiasm have occupied the first place in the development of phytosociology, after having rightly acknowledged the great merits of Prof. Paczoski, the Polish pioneer in this field (W. W. Alechin: "Wann und wo ist die Phytosoziologie entstanden?", Botaniska Notiser, Lund, 1924). It is more than fifty years since Prof. Paczoski published his work "Stages in Flora Evolution" (Russian, Wiestnik Jestiestwoznanja, St. Petersburg, 1891). There he laid down the principal outlines of phytosociology so clearly that to-day nothing more can be added or abstracted from these. The term 'phytosociology' was used for the first time in his next work "The Social Life of Plants" (published in the Polish magazine *Wszechswiat*, Warsaw, 1896). By giving the outlines of and a name to the new science Prof. Paczoski deserves a permanent place in the history of phytosociology. As acknowledgment of his great merits, the Polish Botanical Society reprinted his "Social Life of Plants" in the "Biblioteka Botaniczna", vol. 2, Cracow, 1930, published in Polish and English. The term 'phytosociology' has been used by the following authors in chronological order: J. Paczoski in 1896, P. Krylow in 1898, W. Sukaczew in 1915, M. Harper (United States) in 1917, in Scandinavia and Western Europe in 1919.

Researches made in Bialowieza directed his attention to the relation between the number of trees and diameter of the trees at 1·3 m. (to about 4 ft. 3 in.) in pure and mixed woods respectively. Paczoski's curves for the primeval and thinned forests are based on these measurements. These methods have been termed by Paczoski "biological structure of forests". After further investigation they will be of practical importance in forestry. Results have been published in the Polish Forestry Society's Journal *Sylwan* printed in Lwów, and in the standard work "Forest of Bialowieza". In 1930 Paczoski was sent by the University of Poznan to Yugoslavia and Bulgaria for special forest investigations. His very interesting results were published in *Sylwan*.

Prof. Paczoski's death is a serious loss not only to Polish science but also to the scientific community throughout the world.

S. B.

The Right Hon. Lord Glanely

THE RIGHT HON. LORD GLANELY, whose death occurred on June 28 as a result of enemy action, was president of the Court of Governors of the University College of South Wales and Monmouthshire. A Cardiff shipping magnate and head of the Tatem Shipping Company, he had always maintained a special interest in University College, Cardiff. After the War of 1914–18, when a special appeal was launched for the completion of the buildings on the new site in Cathays Park, he made a magnificent donation of £100,000 to that fund. This was allocated to the provision of the "Tatem Chemical Laboratory" and to the erection of a wing of the College to be devoted to the study of agriculture, a subject in which the late Lord Glanely was specially interested. This wing now houses the Advisory Departments of Agricultural Zoology, Agricultural Botany and Veterinary Science. In 1930 Lord Glanely made a gift of £2,000 to found two scholarships in memory of his wife, to be awarded in the first place to the children of parents who are or have been employed at or about Cardiff Docks. In this way he indicated his special interest in the welfare of the workers in the industry from which he derived his fortune. At the time of his death Lord Glanely was serving his third five-year term of office as president of University College, Cardiff. The College mourns the loss of a generous benefactor whose sympathy for, and interest in, its progress had extended over twenty-five years, the most difficult and important in its history.

WE regret to announce the following deaths:

Prof. Raymond Dodge, emeritus professor of psychology at Yale University, member of the U.S. National Academy of Sciences and president in 1916–17 of the American Psychological Association, on April 8, aged seventy-one.

Mr. E. C. Groesbeck, metallurgist of the Division of Metallurgy of the U.S. Bureau of Standards, on May 8, aged sixty-one.

Mr. G. C. Lloyd, secretary of the Iron and Steel Institute during 1908–34, on July 10, aged eighty-one.

Mr. W. F. Reynolds, chief of the Section of Triangulation of the Division of Geodesy of the U.S. Coast and Geodetic Survey, on May 1, aged sixty-one.

Prof. John Harrison Skinner, professor of animal husbandry and dean emeritus of the School of Agriculture of Purdue University, on April 28, aged sixty-eight.

Prof. A. N. Talbot, professor of municipal and sanitary engineering in the University of Illinois, on April 3.

Prof. W. H. Young, F.R.S., formerly professor of mathematics in the University of Wales, aged seventy-eight.

NEWS and VIEWS

National Institute of Agricultural Engineering

THE Institute for Research in Agricultural Engineering, University of Oxford, has been taken over by the Ministry of Agriculture to form the nucleus of a new national institute which has been established at Askham Bryan, near York. The general function of the National Institute of Agricultural Engineering will be to foster the development and better utilization of agricultural machinery of all kinds. Its work will be organized in three main departments. The Agricultural Department will provide a clearing-house for information about machines and methods for the benefit of both farmers and manufacturers; and will aim both at bringing equipment needs to light and at suggesting the means by which they can be met. The Engineering Department, which is to be adequately equipped with drawing office and workshops, will be concerned directly with design and improvement. In the case of new inventions, it will provide the necessary link between the original idea and the device which is ready for development, by undertaking the final stages of design and constructing prototype machines. The Field Station Department will be equipped to carry out whatever tests, trials or demonstrations may be required. One of its main duties during wartime will be to try out, adapt and demonstrate in other districts, labour-saving devices and methods which individual farmers up and down the country have worked out for themselves. The Institute will be guided in its work by the Agricultural Machinery Development Board, which was set up earlier in the year under the chairmanship of Lord Radnor. The director of the new Institute is Mr. S. J. Wright, formerly director at Oxford.

Planned City Growth

THE extent to which Mr. F. J. Osborn's admirable statement of the main essentials of planning, so far as they affect the ordinary citizen, originally written in 1918, is still valid to-day is a tribute to his powers of analysis and exposition (New Towns After the War. By F. J. Osborn. Revised edition. Pp. 72+8 plates. (London: J. M. Dent and Sons, Ltd., 1942. 4*s.* 6*d.* net.) It is also at least in part a reflection upon the general failure to apply those principles or even to learn from the bitter experience of the decade after the War of 1914–18. On both counts the 1942 edition deserves a warm welcome, and the new matter included, notably the illustration of the way in which Welwyn Garden City exemplifies the original thesis or formula, and the brief but well-chosen book list, enhance its value. The book is a concise re-statement of the argument for building new industrial towns, surrounded by country belts, as part of the reconstruction programme. Stressing the necessity for a national plan and criticizing the absence of policy which permitted the expansion of a few great cities at the expense of the countryside and of the smaller towns of Britain, with grave effects on the lives of town-dwellers and the efficiency of industry, it outlines broadly a policy commensurate with the needs of the time, the soundness of which is emphasized by the fulfilment of many of the author's predictions as to the trend of unplanned city-growth.

The close connexion of housing with public health, with transport, with problems of industrial and agricultural organization, with child welfare and education, national and local government and every aspect of the civic and cultural life of the community, leads Mr. Osborn to insist that there is a maximum size for a modern town. He advances the formula that a town should be of a population large enough to allow of efficient industrial organization and full social activity, but no larger. The urban area should be limited to a size requisite to house this population well, and should be surrounded by a zone of open land large enough to possess a distinctively rural and agricultural character. The whole of the land, including the urban area and the rural zone, should be owned and administered in the interest of the community. The application of this formula is well illustrated by reference to Welwyn Garden City, the foundation of which by Sir Ebenezer Howard in 1919 was an outcome of the original publication of the book. Mr. Osborn directs attention to the importance of some of the special problems involved, such as the location of new cities in relation to rural needs, some of which, like that of general control and liberty of individual taste in design, have not yet been fully thought out. The conditions of State support are indicated and Mr. Osborn gives an inspiring glimpse of the possibilities inherent in developments on these lines if the opportunities are used by creative minds alive to the social issues involved.

Dr. A. Yakubov

MELIK-PASHAYEV, chief geologist to the Azerbaidjan Oil Combine, has recently provided the Press Department of the Soviet Embassy in London with some interesting information concerning the career of Akhad Yakubov, vice-chairman of the Azerbaidjan Branch of the Academy of Sciences of the U.S.S.R. As a young man Yakubov's overriding aim was to master the science of geology and place his knowledge at the service of his country. More particularly was he concerned with the applications of geology to the economic exploitation of petroleum deposits. Experience as a technician in the oil fields of Baku and later at Lokbatan gave him a sure practical knowledge of the oil industry, which was implemented by his studies at Azerbaidjan Industrial Institute and at the Azerbaidjan branch of the Soviet Academy of Sciences, where he took his doctor's degree in geological and mineral sciences with honours. While in charge of oil extraction at a new field which was being developed on the slopes of Lokbatan mud volcano, Yakubov became convinced of the fallacy of the then widely held belief that mud volcanoes were incompatible with oil-bearing strata.

Detailed studies lasting over a period of ten years confirmed Yakubov in this view, and between 1934 and 1941 he published eight books elucidating the connexion between mud volcanoes and oil deposits. Summarily, Yakubov believes that "mud volcanoes are a direct indication of the existence of oil- and gas-bearing deposits" and that "the distribution of oil and gas is determined by the same laws as operate in regions where there are no mud volcanoes". His work considerably increases prospects of oil discovery in Azerbaidjan and is of immense practical value in the prosecution of the war against Germany. Early this year Yakubov was decorated with the Order of Lenin and afterwards was awarded a First Stalin Prize. Born in 1908, he is now at the height of his creative powers and plays a leading part in the scientific, political and public life of his country.

Bagasse for the Manufacture of Paper and Board

THE many attempts to utilize bagasse for the manufacture of paper have met with varying degrees of success, partly for economic reasons and partly because the nature of bagasse often renders it suitable only for relatively low-grade products. M. P. Bhargava and A. N. Nayer, of the Dehra Dun Forest Research Institute, have, however, recently approached the problem from the other extreme, namely, that of the manufacture of boards, and in particular of insulation and pressed boards, a large potential demand for which exists in India (*Imp. Council of Agric. Res., Misc. Bull.*, No. 44 ; 1941). The various processes available for the purpose were studied, but defibration in an Asplund-type machine was favoured on the grounds of the low installation and operating costs and of the quality of the product. The cost of afterwards rendering the boards resistant to moisture, fire and insects appears, however, to be disproportionately high. The samples accompanying the bulletin and the test data published in it suggest that, technically, the process is a promising one. The sample of bagasse wrapping-paper also sent is, however, less impressive ; no test data are given, but obviously the fibre length is short, which means low tearing and folding strengths.

A New X-Ray Photographic Paper

MESSRS. ILFORD, LTD., have recently placed on the market, under the name 'Kryptoscreen', a new X-ray paper incorporating its own intensifying screen. Underneath the sensitive emulsion is a layer of extremely fine white pigment which fluoresces under the influence of X-rays. The blue-violet light emitted shortens exposure times and much improves the gradation of radiographs made on the paper. The search for a cheap fluorescent material which neither lowers the sensitivity of the photographic emulsion nor impairs definition has been carried on for many years by the Ilford Research Laboratories. The resulting product provides an economical substitute for film in the radiography of fractures of the extremities and in certain types of industrial radiography. The same fluorescing material has been used to make a 'Brytex Intensifying Leaf' of exceedingly fine grain and medium intensification factor. When both screen and paper are used together, a reduction in exposure to one third of that needed by Kryptoscreen paper alone is possible without any loss of definition.

A New British Orchid

THE flora of the duneland area between Liverpool and Southport (botanically "south Lancashire", vice-county 59, but in all official and local nomenclature "west Lancashire") has always interested botanists well outside the local area owing to the many special forms of plants adapted to the peculiar habitat, and as a subject for plant ecology it much resembles the Flanders coast. Its list of sixteen Orchidaceæ is a special attraction and this has now been extended by the discovery and naming of a new species, *Epipactis pendula* (C. Thomas, *J. Bot.*, Dec., 1941) previously regarded by local botanists as *E. dunensis* (Godfrey, "British Orchidaceæ" ; Green, "Flora of Liverpool"), which in turn had for years been locally considered but an early-flowering variety of the common broad-leaved helleborine, *E. latifolia*, but with smaller, greener, less-expanded flowers. The new species was found and described in some numbers from Formby and appears to prefer the clearings by the woods, whereas *E. dunensis* proper is more typical of the open dunes.

In 1934 two Liverpool naturalists, Green and Hardy, made a floral survey of these dunes for Flora's League in the hope of creating a plant sanctuary, and this orchid was noted growing abundantly in and by the thinner pinewoods, but it was regarded as a woodland variation of *E. dunensis*. The description of the new species notes as characteristic its sturdy growth, small, opposite, arched and wavy-edged leaves, raceme of numerous pendulous flowers often tinted brown on the outside, flowers large and frequently wide open ; of forty-five plants at Formby a few had more than one flowering stem. The type is in the British Museum herbarium. If all the plants previously thought to be woodland forms of *E. dunensis* are the new species it seems safe from extermination, and was possibly evolved from *E. dunensis* since this coastal area was afforested in 1889.

Ultra-violet Radiation

A SUMMARY of the uses of ultra-violet radiation with special reference to lethal effects is given by J. R. Harris in the *Electrician* of July 10. The 'near' ultra-violet region, 3,200 A. to 4,000 A., is used for photographic and fluorescent effects, the source generally being the ultra-violet 'black' lamp, which emits a maximum radiation at 3,650 A. The 'middle' band, 2,800 A. to 3,200 A., represents the therapeutical region which produces erythema ; lamps emitting this radiation are the so-called sunlamps and are widely used as a tonic treatment in welfare centres. Rays in the 'far' ultra-violet region, 2,000 A. to 2,800 A., are lethal to bacteria; the most suitable source is the quartz mercury-vapour discharge lamp large numbers of which are used in the United States for sterilizing.

The lamps have been given the following applications. Germicidal lamps have been installed in air-ducts, particularly those of air-conditioning schemes. In the ward of a children's hospital, germicidal lamps have been placed in concentrating reflectors and mounted on the ceiling between the cots to prevent the free passage of bacteria by the presence of the invisible 'lethal' curtain. Lamps have been installed with successful results in a mattress factory for sterilizing the cotton, the method proving cheaper than sterilizing by placing the cotton in a room containing formaldehyde fumes. A New York hotel recently purchased a specially constructed unit of four 15-watt germicidal lamps for use in bathrooms, the whole unit being designed so that the ultra-violet rays reach the floor and walls; the lethal efficiency is stated to be 99 per cent. Small sources have been installed over the counter of a bank so as to produce an invisible 'purification wall' between cashiers and customers.

A New Circuit Continuity Test

A. F. BURNS, in an article on testing of the crossbar system of telephony (*Bell Lab. Rec.*, **20**, No. 9 ; May, 1942), points out that in dialling systems a talking connexion is established through a large number of contacts, and it is desirable to test for ensuring that after the circuit is closed through to the called subscriber, there will be no open circuits in the offices through which the call passes. With the crossbar system, the sender makes a continuity test t the calling office and at the originating office, but it was found to be impracticable to provide a suitable outine testing procedure for the terminating office because of the multiplicity of paths that any paricular call might follow. It was decided, therefore, o arrange the terminating marker to apply a coninuity test for each call to make sure, before it is disconnected, that a circuit is completed to a subscriber line.

Briefly, the method consists in sending grounded 20-cycle current through the central-office contacts, out on one side of the subscriber line, through the station ringer, or signal, and to ground either at the subscriber station or at the central office. The difficulty associated with widely varying circuit capacitances and resistances was overcome by taking advantage of the difference in phase between the current flowing through the office capacitance and that flowing over the subscriber line, which latter is chiefly resistive under extreme conditions. In the extreme case, when the ground capacitance is zero and the circuit is closed, the current that flows is in phase with the applied voltage, whereas when the capacitance from the 20-cycle supply to ground is a maximum and the circuit is open, the current flowing is 90° out of phase with the applied voltage. An open circuit with high leakage may thus draw more current than a closed circuit with low leakage, but the angular displacements of the currents with respect to the applied voltage are very different. The new test is based upon this fact, and current flowing in the test circuit is determined from the voltage drop across a condenser in series with the subscriber line. The article describes the test circuits and apparatus in detail and indicates the criteria governing the test.

Philosophy in the *Philosophical Magazine*

ALTHOUGH physics is regarded as one of the exact sciences, exactitude was not always found in the titles of its journals. For many years *Science Abstracts* was regarded as an adequate title for the journal now known as *Physics Abstracts*, and the *London, Edinburgh and Dublin Philosophical Magazine and Journal of Science* has published many more papers in physics than in philosophy. In the May number of the latter, however, four of the seven papers are mainly philosophical. Prof. E. T. Whittaker gives a stimulating discussion of "Some Disputed Questions in the Philosophy of the Physical Sciences", using well-chosen analogies. Attention is naturally given to the attempts of mathematicians to discover 'facts' without the use of experiment or observation. As mathematical symbols are not used, the paper is suitable also for the general reader. The other three papers deal with the thorny subject of dimensions. In a brief note, Dr. Norman Campbell points out that writers on the subject are apt to ignore much of the vast literature because "anyone who attempted to summarize the literature would become involved in so many controversies that he could get no further". Since assignment of dimensions is a means to an end, and not an end in itself, writers are urged to state explicitly what end they have in view and how that end is served by the considerations presented in their writings. In a paper of twenty-four pages, Prof. H. Dingle attempts to relate the subject to more fundamental and universally acceptable ideas. Twelve definitions and postulates are given as a set of principles upon which discussion of dimensions may be based. The third paper, by Dr. G. B. Brown, is a reply to some criticisms of Prof. Wilson upon a recent paper on dimensions published originally in the *Proceedings of the Physical Society*, **53**, 418 (1941).

Potentialities of the Forests of Latin America

PROF. S. J. RECORD of the School of Forestry, Yale University, raises the question of the utilization of the "enormous areas" of potentially commercial forest in Latin America in a brief article in *Tropical Woods* (No. 70. Yale University; June, 1942) that deserves wide consideration. He points out the reasons for the lack of demand for tropical lumber. Tropical timbers are different from those growing in the north temperate zone; they may not be inferior but their technical properties are unknown to the consumer. Private commercial concerns naturally do not face the trouble and expense involved in trying out the utility of the new wood for their purpose and they have no guarantee of continuity of supply of the new type. The plain lack is that of subsidized laboratory facilities to make pilot tests on the utility of available timber, to trace defects in supply to their source, to encourage good forestry management and exploitation and to educate the trade in the utilization of the new wood in manufacturing processes. Prof. Record concludes: "Science and Engineering together can find a way to use the tropical forest as a whole and make it a perpetual source, not only of plywood and lumber, but also of unlimited quantities of cellulose, a basic material with a myriad actual and potential applications in industry."

Discovery of the North American Flora

MANY kinds of trees and shrubs now used in forestry and gardening owe their introduction to the pioneer journeys of David Douglas (1799–1834). These early botanical explorations form the subject of a recent paper by F. R. S. Balfour (*J. Roy. Hort. Soc.*, **67**, Parts 4 and 5; April and May, 1942). Douglas's journey to the North Pacific Coast in 1824 was backed by the Royal Horticultural Society, and resulted in the introduction of such garden favourites as *Ribes sanguineum* and *Berberis aquifolium*. New conifers were later discovered, namely, *Pinus nobilis*, *P. amabilis*, *P. lambestiana*, *Larix occidentalis*, *Thuja plicata* and many others. Neither shipwreck nor illness deterred this intrepid botanist, and while most of his journeys were made in North America, he met a rather strange death during a journey in Hawaii.

Cancer Control

AN annotation in the *Journal of the American Medical Association* of April 18 states that since a cancer control programme was inaugurated fifteen years ago in Massachusetts, about 14,000 patients with cancer, 40 per cent of whom are still alive, have attended the special clinics for the disease. 80·8 per cent of the patients were referred by medical practitioners to the clinics as compared with only 20·1 per cent in the first year of the programme. Between 1927 and 1935, 421 medical men used the tumour diagnostic service as compared with 798 in 1940. As regards the education of the public, the delay between the time of the first recognized symptom of the disease and the time that the patient obtained medical advice averaged 6·5 months in the early years of the programme, whereas between 1936 and 1939 it was 5·3 months and in 1940 4·6 months. In 1932, 31·1 per cent of the fatal cases had never been treated in a cancer hospital, while in 1940 this figure was reduced to 15·6 per cent, indicating that hospitalization for cancer is increasing far more rapidly than cases of the disease.

Biology in Brazil

We welcome the appearance of No. 1 (March, 1942) of Vol. 2 of the *Revista Brasileira de Biologia*, the official organ of the Biological Society of Brazil. The issue runs to 133 pages and contains seventeen papers covering a very wide field of biological subjects including medicine and parasitology. Thus, P. W. Wygodzinsky describes new species of insects of the orders Diplura and Thysanura from Palestine: J. R. Valle and P. R. Souza discuss observations concerning the endocrine system of eighty-four ovoviviparous snakes, and especially the corpora lutea; and F. Feigl and H. Cardoso write on tests for the identification of ascorbic acid. Each volume of the journal is to contain about five hundred pages, comprised in four parts issued in March, June, September and December. The subscription outside Brazil is 4 U.S. dollars, which should be sent to the Secretario da Comissâo de Redaçâo, Mario Vianna Dias, Caixa postal 1.587, Rio de Janeiro, D.F., Brazil.

Health of Ceylon

According to the report of the Director of Medical and Sanitary Services, Ceylon, in 1940, malaria, as in previous years, was the most prevalent disease in the island, about 97,000 cases having been treated in hospitals and 2,994,000 in dispensaries. The chief outbreak occurred in the south-west early in May and continued until the middle of July. In the north-western province an epidemic of dysentery, due to the Shiga bacillus, also started in May. During the year the leprosy survey which was begun in 1933 was completed. The total number of patients was 2,771—2,032 males and 739 females—of whom more than a thousand were segregated in two leper asylums. The whole population of Ceylon is estimated at 5,951,000, The total births in 1940 numbered 212,982, a rate of 35·8 per 1,000; deaths amounted to 122,738, a rate of 20·6. The infant mortality-rate was 149 per 1,000 and the maternal rate 16·1.

Aphids

A short paper by G. Fox-Wilson (*J. Roy. Hort. Soc.*, **67**, Pt. 6; June, 1942) reviews the horticultural significance and control of aphids. Eradication of these pests is often difficult, and one of the reasons is discussed in the paper. Viviparous stem mothers, when subjected to certain contact insecticides, often remain in a comatose state before death actually occurs, but living nymphs are often produced in this condition. Spraying with nicotine is the best control, but Derris and Pyrethrum washes should be employed where the plant parts attacked are to be used for food.

Physics Bibliography

The vital importance of the library as a part of the equipment of a research laboratory is implicitly acknowledged in the *Review of Scientific Instruments* by the attention given to the current literature of physics in each number of the journal. Twice a year special book numbers are issued, and the spring book number (13, No. 4, April, 1942) contains twenty four pages devoted to reviews of thirty-eight books on physics. In addition, a two-page "Condensed Library Guide for the Physicist" gives a summary of the standard sources of reference. Copies of the list for the use of students can be bought in quantity from the American Institute of Physics, 175 Fifth Avenue, New York. The list serves as a reminder of the extent to which physics lags behind chemistry in bibliography. The usual monthly survey, "Current Literature of Physics", deals with the research journals. The latest reference to an English journal appears to be that to the issue of Nature dated February 7.

Announcements

In pursuance of the decision of the Secretary of State for the Colonies to open the administrative service in the Gold Coast to Africans, Mr. K. A. Busia and Mr. A. L. Adu have been selected as assistant district commissioners in the Gold Coast. Mr. Busia, an Ashanti, was born in 1913. He was educated in the Gold Coast, where he graduated in 1939, and at University College, Oxford, where he obtained a B.A. degree. Mr. Adu, a member of the Twi tribe, was born in 1914. He attended schools in the Gold Coast, and afterwards went to Queens' College, Cambridge, where he took a degree in natural science.

The following have been elected to fill vacancies which will occur on the Council of the Institution of Electrical Engineers on September 30 next: *President*, Prof. C. L. Fortescue; *Vice-President*, Mr. P. Good; *Hon. Treasurer*, Mr. E. Leete; *Ordinary Members of Council*, Prof. J. D. Cockcroft, Mr. A. J. Gill, Mr. D. B. Hoseason, Dr. A. H. Railing, Mr. E. A. Reynolds, Mr. H. W. H. Richards, Mr. J. M. Fleming and Mr. C. W. Bridgen.

An extensive list of institutions, societies and research workers in the pure and applied plant sciences in Central and South America has been prepared by the editors of *Chronica Botanica*, in co-operation with the Division of Agriculture of the Office of the Co-ordinator of Inter-American Affairs, Washington, D.C. The list has been published in *Chronica Botanica*, **7**, No. 2 and 3, March and May, 1942 (*Chronica Botanica* Co., Waltham, Mass.). There are about two thousand names in the list, which is the first of its kind.

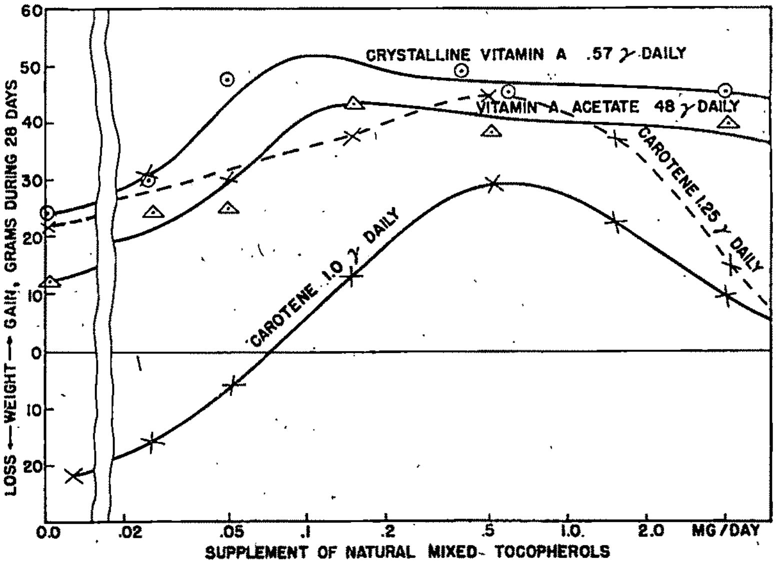
Schuman's, of 20 East 70th Street, New York, have issued a catalogue entitled "Medical Miscellany List E". Attention may be directed to the following items: the "Compendium Artis Medicæ" of Bertucius *alias* Bertuccio or Bertrutius (1537), the "Libri duodecim" of Alexander of Tralles (1556), the "Opuscula anatomica" of Eustachius (1563–64), the first edition of John Hunter's "Treatise on the Venereal Disease" (1786), Morgagni's "De Sedibus et causis morborum" (1820–23), and various early works on anæsthesia. A section on military medicine contains notice of the following important works: George James Guthrie's "Commentaries on the Surgery of the War in Portugal, Spain, France and the Netherlands" (1862), Woodward's "Report on Epidemic Cholera, and Yellow Fever in the Army of the United States during the year 1867" (1868), George M. Sternberg's "Sanitary Lessons of the Spanish-American War" (1899), and Cabanès's "Chirurgiens et blessés à travers l'histoire" (1918).

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Interrelationship of Vitamins A and E

THE effect of vitamin E in preserving vitamin A n oil solution[1] and increasing the store of vitamin A n the liver of the rat[2] suggests that there is an interependence of the two vitamins which hould become apparent in other ways. The failure of Bacharach[3] o confirm all Moore's work on liver torage may be due to differences in ondition and relative quantities mployed, Moore approximating nd Bacharach missing the optinum effect. Using the United tates Pharmacopeia vitamin A ssay method (with olive oil as the pecified "vegetable" oil in the basal iet) and *fixed* quantities of vitamin A, we have examined the effect of itamin E over a *wide* range of osage on the growth of young rats epleted of vitamin A. Some of he results are summarized in the ccompanying graph.



Three forms of vitamin A were chosen: the pure crystalline alcohol, a crystalline ester acetate), and mixed carotenes 90 per cent β-, 10 per cent α-). he vitamin E was a molecular istillate containing 40 per cent of mixed tocopherols,

$$\left\{ \frac{E^{1\text{ per cent}}_{1\text{ cm. }295\text{ m}\mu}}{0\cdot8} = \text{per cent tocopherols} \right\}.$$

The synergistic effect is pronounced, that with arotene striking—a quantity which was unable to upport life alone, inducing good growth when fed ith sufficient vitamin E. The optimum supplement f tocopherols, which is not at all critical, ranges rom 0·1 mgm. daily for vitamin A to 0·5 mgm. for arotene, or about 0·6–3·0 mgm. daily per kgm. of ody weight. The mutual effect persists with high evels of A intake and is most apparent when the itamins are fed simultaneously. Feeding vitamins A and E on alternate days, or giving vitamin E uring the preliminary A-depletion period, seems to iminish the effect.

Benzene extracts of the fæces of rats or humans how a small positive reaction to the Furter-Meyer nd Emmerie-Engel tests. After ingestion of tocoherols, the titres are increased in excess of the uantities fed, though only part of the vitamin E ctivity is recoverable by bio-test. This suggests hat the tocopherols have decreased the oxidation of he lipids in the G.I. tract. Considered with the data n alternate days of feeding, it is concluded that the rst function of vitamin E is to preserve the vitamin A efore and perhaps during intestinal absorption. A econdary effect is the preservation of vitamin A at he site of utilization in the body. Clausen[4] has hown that the transfer of vitamin A to the fœtus om the mother during pregnancy occurs chiefly hrough the medium of carotene. One effect of itamin E deficiency may be the lowering of blood rotene levels in the pregnant rat below that compatible with life of the fœtus. Consequently, the anti-sterility test may be influenced by the administration of carotene and perhaps by vitamin A. A preliminary assay has furnished the following data:

Mixed tocopherols fed*	Vitamin supplement fed	Litter efficiency
1·36 mgm.	None	14 per cent
,,	,,	0 ,,
,,	Vitamin A 100 γ	14 ,,
,,	β-Carotene 300 γ	43 ,,

* In the laboratory where this assay was performed, a dose of 1·0 mgm. synthetic α-tocopherol is considered necessary to give a 50 per cent litter efficiency.

In the case of the rat on the sub-optimal A–E diet, the generalization may be hazarded that an acute shortage of either vitamin will involve deficiency symptoms of the other. Indeed, if a general function of vitamin E in animal nutrition is that of intestinal antioxidant, vitamin A may not be the only labile substance rendered more available to the body. Clinical evidence of moderate E deficiency may well be manifested in apparently unrelated deficiency symptoms.

It would seem necessary to modify the accepted methods of bio-assay of the two vitamins, retention of β-carotene as the international standard of vitamin A, becoming something of a farce. A comparison of United States Pharmacopeia Reference Oil II with carotene could, by suitable juggling of the E content of the diet, show apparent potencies anywhere from 700 to 4,000 international units, the difference between the two scales becoming unimportant.

It would also seem desirable to follow the A–E synergy with animals other than rats. Studies under way with mink and related fur-bearing animals are so far positive. Should the effect be found significant with farm animals and humans, the question of preserving or supplementing vitamin E in feed will rank in importance with retaining carotene or adding vitamin A. In human nutrition the doubts as to whether a well-balanced diet can supply optimal amounts of vitamin A can be relieved by attention to the vitamin E content. Judged solely from our experiments with rats, the optimal human intake would be 50–200 mgm. mixed tocopherols daily. It seems unlikely that the diet—especially the war-restricted diet—contains these quantities. A supplement of 50 mgm. would provide a total intake not far from the optimum.

The above work, to be reported fully elsewhere, is being repeated with the three pure tocopherols and extended to other animals than rats—of which, to date, about 1,500 have been used without encountering assays at variance with a positive A–E synergy.

Parsley as a Rich Source of Vitamin C

IT has been pointed out by Widdowson and Allington[1] that the present restriction of citrus and other fruits in the diet of the middle classes has not been compensated for by an increase in the amount of vegetables eaten, therefore the vitamin C intake has been reduced to half that consumed by the same families in 1935.

Bourne[2] has pointed out the seriousness of the situation that would arise in the event of a failure of the potato crop; although he thinks this improbable. There is no doubt that a very large percentage of the working-class population rely for their source of vitamin C upon the boiled potato, so that a partial failure of the crop with consequent local shortages would reduce the vitamin C intake to a dangerously low level.

While perhaps frank scurvy would not make its appearance, the increased liability to infection when the diet was low in vitamin C might lead to a very serious loss of working hours by workers on essential war work, especially in an epidemic.

It seems to me, that if the population cannot be induced to increase their consumption of green vegetables, the replacement of these and citrus fruits by something in the diet with a very high content of vitamin C is of importance in safeguarding the health of the public.

Apart from the pure crystalline vitamin, the choice should be something which is available, or could be made available, all the year round, and which could be easily grown by a very large percentage of the population, and, still more to the point, something with which they are familiar.

The high figure of 280 mgm. per 100 gm. has been recorded for parsley grown in India[3], 196 in South Africa[4] and 176 and 180 in America[5]. The ascorbic acid content for picked leaves of parsley grown in Cambridgeshire is shown in Table 1. The leaves were ground and extracted with trichloroacetic and metaphosphoric acid, and quickly titrated with 2 : 6-dichloro-phenol-indophenol, using the micro method of Birch, Harris and Ray[6]. Reduction by hydrogen sulphide showed no increase, and treatment by mercuric acetate[7] no decrease, in the figures obtained by direct titration.

It will be seen from Table 1 that the average of 279·5 mgm. of ascorbic acid per 100 gm. for nine different samples of English parsley is somewhat higher than the averages given by Olliver[8] for ripe black currants, and places it in the front rank antiscorbutics. Although no biological assay has be done, Harris and Olliver[9] have confirmed the agre ment between results obtained by this chemic titration method and in biological assays. It remai to be seen whether there are seasonal variations, a if the age of the leaves or the richness of the s influences the content of the vitamin.

TABLE 1.

Date	Ascorbic acid (mgm. per 100 gm.)	Ascorbic acid (mgm. per oz.)	Water (per cent)
1942			
April 13	307·68	87·05	78·66
,, 14	250·00	70·80	77·52
,, 16	250·00	70·80	83·08
,, 17	266·40	75·55	81·08
,, 28	275·84	78·22	82·40
May 1	291·20	82·59	78·42
,, 4	291·20	82·59	80·74
,, 4	333·28	97·54	78·96
June 7	250·00	70·80	80·96
Average	279·51	79·54	80·20
Stalks April 14	66·40	18·83	85·14

The optimum amount of ascorbic acid required an adult weighing 70 kgm. (11 stone) is abo 60 mgm. a day[10], while half this amount will prote against any manifestations of scurvy[11]. It follow therefore, that ½ oz. of parsley eaten a day will gi complete protection with a diet lacking the vitami Unfortunately parsley is very bulky for its weigh ½ oz. of picked leaves is a small handful, but diminished to a heaped tablespoonful by choppin

It would be better to encourage the eating of t small picked leaves, and so preserve all the vitamin but if the parsley is not chopped wet, and a sha stainless steel knife is used, the loss is only of the ord of 20 per cent, and there is still enough vitamin le in ½ oz. for protection. The vitamin is irreversib oxidized by the oxidases at the cut surfaces, so t finer the parsley is chopped the greater will be t loss. After the initial loss there is no further decrea upon keeping for three hours. This has also be shown for cabbage by Pyke[12] and confirmed Lampitt *et al.*[13].

TABLE 2.

Time after chopping	Original ascorbic acid content (mgm. per 100 gm.)	Ascorbic content after chopping (mgm. per 100 gm.)	Loss per 100 gm.
30 min.	250·00	200·00	20·0
30 ,,	250·00	210·48	15·8
30 ,,	275·84	222·00	19·5
3 hr. 0 min.	275·84	222·00*	19·5

* This sample reduced by hydrogen sulphide showed no increase

With the growing trend to desiccate foodstuffs wi a presumable loss of vitamin C, these results ne emphasis. It should also be remembered that parsl is very rich in iron, containing 1·42 mgm. of availa iron per oz.[14].

The crop production could easily be increased, f parsley can be grown by anyone with a garden allotment. It is not unsightly as an edging to flower border.

If the population could be induced to grow mo parsley and include it in their diet, it would be of great benefit to their health, and also a wise step to take. If there were a shortage of potatoes, parsley would act as a valuable source of vitamin C served with a small ration of boiled potatoes.

There are many culinary uses for parsley, and instead of the usual 'sprinkling', much more could be used. More use could also be made of it alone, or with meat, meat pastes or 'Marmite' in sandwiches. It is best to use it naturally, fresh from the garden; but in order to keep it ready for use, it should be washed, shaken to remove water and kept with the stems in water. I found no loss of the vitamin after keeping in this way for two days.

One of the best ways to use it for replacing citrus fruits is to make 'parsley lemonade' in the following simple way. Take 1 oz. of picked leaves (two handfuls) and press down in a jug; pour on to this ½ pint of boiling water and allow to stand two minutes. Now strain through a piece of muslin (or calico) and get all the parsley into the muslin, squeeze out all the liquid you can, and cool. The extract is slightly cloudy, lemon yellow in colour and contains 40–56 mgm. of ascorbic acid. This is equivalent in its vitamin content to the juice from an orange of average size. The vitamin content can be increased by using up to 2 oz. of parsley to ½ pint of water. A clear extract is obtained if the parsley is not squeezed, but it contains only about half the amount of ascorbic acid. It is not unpleasant to the palate, since there is only a slight flavour of parsley. If desired, it can be flavoured in a variety of ways to suit the taste, such as by using a lemonade preparation which has not been made from lemons.

Some typical figures obtained from 1 oz. of parsley by squeezing were 43·08, 56·80 and 51·64 mgm., and by straining only, 27·54 and 26·66 mgm.

I suggest that more parsley be used in preparing snacks and meals in canteens, British Restaurants, schools, etc.

Proliferation-promoting Activities of Extracts from Ultra-violet Injured Yeast Cells and of Bios Components

NUMEROUS papers from these laboratories have dealt with the production of proliferation-promoting factors ('intercellular wound hormones') by cells subjected to various injuring agents. It seems warranted to believe that these substances are produced by living, injured cells as a response to injury and are not simply dead-cell disintegration products[1]. The question of the nature of these materials is of great interest. It might be assumed that they are merely normal growth substances produced or released in greater quantities under the conditions of injury, or it is possible that they represent specific 'injury substances'. Two lines of inquiry have been undertaken to answer the question: (1) chemical and spectrographic studies, which suggest a nucleic acid-like nature for the wound hormones and which definitely show that substances of this type are produced in greater quantity as a result of injury[2]; (2) comparative growth studies, on the wound hormone preparations and known growth substances. The present note is concerned with the latter.

In the earlier work assays for proliferation-promoting activity of wound hormone preparations on yeast were carried out in Reader's medium[3], an incomplete medium as judged by present standards. In experiments to be published in detail elsewhere[4] a wound hormone preparation (prepared by the full ultra-violet irradiation of a suspension of 917 gm. of Fleischmann's bakers' yeast in 10 litres of 0·85 per cent sodium chloride solution for twenty-seven hours; details in paper cited) was assayed for its effect on the proliferation of a strain of *Saccharomyces cerevisiœ*, isolated from Fleischmann's bakers' yeast, in the following media: (1) Reader's; (2) Reader's plus a bios supplement; (3) Reader's plus a bios supplement plus twenty amino acids; (4) Williams's[5]; (5) Williams's plus bios; (6) Williams's plus bios plus amino acids. The bios supplement consisted of inositol, 100 γ per c.c.; thiamin hydrochloride, 0·8 γ per c.c.; biotin, 0·002 γ per c.c.; calcium (+) pantothenate, 0·12 γ per c.c.; vitamin B_6 hydrochloride, 0·8 γ per c.c. The amino acids were asparagine, alanine, arginine, aspartic acid, cystine, glutamic acid, glycine, histidine, hydroxyproline, isoleucine, leucine, lysine, methionine, phenylalanine, proline, serine, threonine, tryptophane, tyrosine and valine, each in concentrations of from 0·06 to 0·48 mgm. per c.c.

Media (3), (5) and (6) gave the best growth, which represented about a 1,100 per cent increase over that in Reader's medium. The similarity of growth in media (5) and (6) is apparently due to the inclusion of asparagine in Williams's medium. The beneficial effects of the bios components and amino acids were thus quite evident. Addition of the crude wound hormone preparations in every case gave increased growth, showing that, while part of the activity of the wound hormone preparation is no doubt due to the known bios factors, a definite residual activity is due to factors other than these. This increased growth effect of the wound hormone was detectable in concentrations of the crude preparation as low as 0·5 γ per c.c.

We have now had an opportunity to extend these observations somewhat. Indications are that a large portion of the amino acid effect is due to asparagine, and we have found that the mixture of the twenty amino acids can be replaced with almost complete satisfaction by the six amino acids: arginine, asparagine, aspartic acid, glutamic acid, leucine and lysine. We have further supplemented the media with the following (in γ per c.c.): riboflavin, 1; uracil, 1; choline hydrochloride, 1·5; acetyl choline bromide, 1; ethanolamine, 5; nicotinic acid, 5. The addition of these substances seems to have no, or relatively slight, effect on the growth of our strain of yeast and they do not lessen the activity of the wound hormone preparation. Addition of ρ-aminobenzoic acid in concentrations of 2·5 to 10 γ per c.c. did not increase the yeast crop and, in some concentrations, gave a suggestion of slight inhibition, which may not be significant.

The work may be summarized as follows: Cell-free wound hormone preparations from ultra-violet injured yeast cells maintain a considerable degree of their proliferation-promoting potency for yeast in media containing not only the required inorganic constituents and sugar but also containing amino acids, inositol, thiamin, pantothenic acid, biotin, vitamin B_6, riboflavin, uracil, choline, acetyl choline, ethanolanine, nicotinic acid and ρ-aminobenzoic acid. The wound hormone preparation therefore contains active substances in addition to these.

Bacterial Reduction of Tetrathionate

The power of reducing nitrate is widespread among micro-organisms, while the reduction of sulphate is restricted to a few species[1]. It has long been recognized, however, that many bacteria are able to reduce less highly oxidized inorganic sulphur compounds (tetrathionate, thiosulphate, sulphite, etc.) to hydrogen sulphide[2]. In the course of attempts to improve selective media for isolating Salmonellas and *Bact. typhosum* from excreta, we have found that, so far as some organisms are concerned, the tetrathionate is first reduced to thiosulphate. This reaction takes place rapidly and quantitatively, and estimations at different stages show that the molecular concentration of the thiosulphate formed is twice that of the tetrathionate which has disappeared, in agreement with the equation:

$$Na_2S_4O_6 + 2H \rightarrow Na_2S_2O_3 + H_2S_2O_3.$$

The subsequent further reduction of thiosulphate to hydrogen sulphide is, in comparison, so slow that the reduction of tetrathionate can be followed accurately by direct iodometric titration of the thiosulphate, provided that the high acidity developing from accumulation of thiosulphuric acid is controlled by a phosphate buffer.

The ability to reduce tetrathionate is possessed by most of the common Salmonellas, such as *Bact. typhosum, paratyphosum B* and *C, typhi-murium, thompson, reading* and *dublin*, and by members of the Proteus group, but not by most other fæcal organisms tested including *Bact. coli, Bact. aerogenes* and dysentery bacilli.

Our experiments have been done almost entirely with *Bact. paratyphosum B*. The reaction can be followed in growing broth cultures, or by the use of thick washed suspensions. Unless, however, some suitable hydrogen donator such as mannitol or glucose is added to the washed suspensions, the reaction proceeds comparatively slowly. When prepared from organisms grown on plain nutrient agar, washed suspensions show an apparent lag phase before the rapid reduction of tetrathionate begins. This lag phase is not present when the organisms have been grown on agar containing tetrathionate. Suspensions grown on plain agar can be 'adapted' to reduce tetrathionate without the initial lag phase by incubation for only three or four hours with tetrathionate and mannitol without additional source of nitrogen.

The reaction appears to be similar to other known types of anaerobic oxidation processes[3] and we have evidence that it involves a hydrogen donator (for example, glucose or mannitol), a specific dehydrogenase, a heat-stable co-enzyme-like factor present in tryptic digest broth and acting as a hydrogen carrier, a reducing enzyme mechanism, and a hydrogen acceptor (tetrathionate). The 'adaptive' effect mentioned above, taken in conjunction with the fact that tetrathionate reduction is restricted to certain organisms, strongly suggests a true acceptor specificity.

The discovery of this system is of interest from several points of view:

(1) It has brought to light certain facts of obvious importance in any attempt to explain the selective action of tetrathionate in media for isolating Salmonellas, etc.

It is significant that, in general, organisms which actively reduce tetrathionate are able to grow well in media containing it in relatively high concentration, and that, in competitive growth such as occurs in cultures from fæces, tetrathionate selects those organisms which can reduce it. The reason may be partly that the ability to reduce tetrathionate provides these with a mechanism of energy release not available to other organisms. Further, it is of interest that the substance produced in the bacterial reduction of tetrathionate is thiosulphate, which can be shown to be much less toxic than the tetrathionate from which it is formed. It is not clear, however, whether in mixed cultures this would operate entirely in favour of the tetrathionate reducers.

(2) It provides an interesting example of an oxidation mechanism of a kind known to be present in facultative anærobes[4], and especially likely to be of value to tetrathionate reducers under conditions of low oxygen tension.

(3) It affords an opportunity of investigating the important questions of acceptor specificity and enzyme adaptivity.

(4) The simple titration technique, though limited in application, is an accurate and convenient method for the study of enzyme kinetics.

It is intended to publish shortly a fuller account of this work.

THE GAS INDUSTRY IN GREAT BRITAIN AFTER THE WAR

THE Institution of Gas Engineers held its seventy-ninth annual meeting in London on June 10, under the presidency of Sir Frederick J. West, of Manchester. The main business was the discussion of six short papers dealing with the place of the gas industry in meeting the post-war needs of Great Britain. Throughout the papers ran an emphasis on the need for greater and more thorough education of the personnel of the industry under the conditions of the future. Prof. D. T. A. Townend reviewed the development of university education since the industry applied the Livesey Fund in 1910 to endow a chair in coal gas and fuel industries in the University of Leeds. Recently the University has extended and widened the curriculum by incorporating courses in chemical engineering.

Mr. E. V. Evans, of London, vice-president, gave an account of the progress and intentions of the Gas Research Board established shortly before the outbreak of war. The gas industry of Great Britain can claim a long and effective experience in sponsoring co-operative investigations for the common good, but on a scale which was long felt to be inadequate to meet present and future needs. The new Board was devised to provide for great and necessary developments, but for obvious reasons these have been hindered by the War. Much of what has been done is of a nature which precludes publication.

To-day the most important technical question before the gas industry is the choice between carbonization and complete gasification of coal. In the future, will coal be carbonized in retorts to yield both gas and coke, or will the main product be gas only and no coke ? The possibility of complete gasification of coal under pressure has been shown to be technically possible, but it remains to be shown to be commercially feasible. Success is of great national importance. The industry would be free to use almost any class of coal, free to control the amount of coke produced, and independent of imported mineral oil for the enrichment of water gas. The War has delayed the search for the answer to this problem, and much depends on the answer.

If it is shown possible to convert coal into a suitable gas without coke residue and at an acceptable price, then consumers might reach the fortunate position of those in countries with supplies of natural gas. If this quest is unsuccessful, then the industry must organize itself to supply a combination of gas and coke. The industry has already gone far to inform itself of the size of the problem. In London it has been shown from fuel bills that householders of low purchasing power need 274 therms of 'useful' heat, that is, gross heat in fuel consumed with a correction for efficiency of utilization. Mr. E. Crowther, of Newcastle, in a paper advocating the use of gas for supplying all the heat needs of householders, recorded experience with many houses specially designed and equipped for the purpose. Fuel bills show that in Newcastle the corresponding figure is 316 'useful' therms. With the tariff charges applied the total costs were of the same order as those found when the dwellings were heated by older methods.

Dr. Harold Hartley, of Birmingham, voiced the views of those who envisage the joint use of gas and coke. At present, gas is used in some measure by the great majority of householders, primarily for cooking. For space-heating its use is mainly for intermittent needs, and the bulk is supplied by solid fuels, coke yielding the cheapest service. If, however, gas were available on a two-part tariff comparable with that in the telephone service, then a very large increase in the use of gas for space-heating could be expected. For water-heating the present growth of consumption of coke will continue. It is believed that 60 per cent of domestic fuel used in Great Britain is bituminous coal, and the use of much coal is likely to continue for many years. Unless means for burning coal smokelessly can be devised, the only hope for the abatement of domestic smoke will depend on the extension of the production of gas and coke by carbonization. While there will always be some who can and will satisfy all the needs for domestic heat by electricity, Dr. Hartley thinks there will be only a limited development of the 'all electric' house. To-day the coal industry ranks first as the source of domestic heat supplies in Great Britain, but he believes that, given a suitable system of charging, the gas industry would in our lifetime attain the leading position.

The two other papers concerned more technical matters. Mr. T. C. Finlayson, of London, discussed methods for promoting efficiency and, therefore, fuel-saving in the production of gas. Dr. E. A. C. Chamberlain dealt with the same problem as it appears in the use of gas in industry—to-day enormously increased by war conditions. Gaseous fuels in furnaces offer great conveniences and possibility of fuel-saving in furnaces. This very ease of use and effortless control, however, offers a temptation to effortless and unnecessary consumption. His paper dealt with the potential savings by scientific control.

SHOOT ORGANIZATION IN DICOTYLEDON AND MONOCOTYLEDON

A PAPER by C. P. Majumdar (*Ann. Bot.*, 6, No. 21, January, 1942) on the organization of the shoot of *Heracleum Sphondylium* leads to an interesting comparison of the mode of growth of the dicotyledon and the monocotyledon. One distinction frequently made between the two is that the leaf has a comparatively narrow insertion in the dicotyledon, and as a result room is found for two cotyledons around the embryonic apex ; in the monocotyledon the leaf insertion is wide, often completely encircling the axis, and there is only one cotyledon. Two families of Dicotyledons, the Ranunculaceæ and Umbelliferæ, are characterized by unusually wide leaf insertions, and it is suggestive that all the best authenticated cases of monocotylous dicotyledons have been reported from these families.

Majumdar's examination of the development of the vegetative shoot of Heracleum directs particular attention to the effect of this wide leaf insertion upon the development and anatomy of the shoot, and once more to the remarkable 'leaf cushions' and 'bud cushions' which are one characteristic result of this feature of the umbellifer shoot. But more general interest, perhaps, is attached to the interesting analysis of the axial structure in this type, which, in spite of the multi-lacunar leaf-gap, due to the large number of trace strands entering the axis from the one wide leaf insertion, has still the single vascular ring characteristic of the dicotyledon instead of the scattered bundle structure which would be associated with the entry of similar numerous trace strands into a monocotyledon axis. The distinction seems to be linked with the fact that in the dicotyledon the vigorous growth activity associated with the development of the leaf primordium is expressed in increase in the pro-vascular meristem. As a result the main structural features of the leaf, midrib and main veins correspond with the pattern of venation, while superficial ridges on the axis show a similar correlation with the pattern of the vascular ring. In the monocotyledon, on the other hand, both encircling leaf and subtending axis progress in size mainly by increase in the parenchymatous semi-meristem in which the pro-vascular elements are embedded. The latter keep pace with the growth of the tissues around but do not dominate it and so impress the vascular pattern on the general organization. Thus a leaf midrib, if present, may show little correlation with the course of the veins and in the axis the vascular strands lie dispersed among the ground tissue.

The author discusses how these different methods of development affect the interpretation of the shoot of dicotyledon and monocotyledon as an articulate structure, built up of coalescing 'phytons'.

FORTHCOMING EVENTS

Wednesday, July 22

Institute of Chemistry (Birmingham and Midlands Sections) (at the Chamber of Commerce, New Street, Birmingham), at 6 p.m.—Prof. W. N. Haworth, F.R.S.: "Structure and Pattern in Carbohydrates".

Saturday, July 25

Nutrition Society (joint meeting with the Food Group, Society of Chemical Industry) (at British Medical Association House, Tavistock Square, London, W.C.1), at 11 a.m.—Conference on "Dehydration of Foods and the Effect on their Nutritional Value".

Friday and Saturday, July 24-25

British Association (Division for the Social and International Relations of Science) (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 10 a.m.—Conference on "Mineral Resources and the Atlantic Charter".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned :

Lectureship in Mechanical Engineering—The Principal, Heriot-Watt College, Edinburgh (July 27).

Lecturer (ungraded) in Biochemistry—The Registrar, The University, Liverpool (July 30).

Chief Assistant Engineer—The Clerk and Manager, West Midlands Joint Electricity Authority, Phœnix Buildings, Dudley Road, Wolverhampton (endorsed 'Chief Assistant Engineer') (July 31).

Regius Professor of Engineering at Edinburgh University—The Private Secretary, Scottish House, Fieldon House, 10 Great College Street, London, S.W.1 (September 7).

Mistress to teach Mathematics (mainly Arithmetic and Book-keeping)—The Headmistress, Day Technical School for Girls, Fort Pitt, Chatham.

Master well qualified in Mathematics and Engineering Science—The Principal, Technical Institute and Junior Technical School, Gravesend.

Teacher for Day and Evening Engineering Classes, and a Teacher for Engineering Workshop Practice and Metalwork—The Principal, County Technical College, Gainsborough, Lincs.

Assistant (male or female) to the Public Analyst—The Secretary, Health Department, Grey Friars, Leicester.

College of

UNIVERSITIES IN WAR-TIME

THE extent to which the universities of Great Britain are addressing themselves to the war effort is well indicated in an admirable series of articles which has appeared in *Britain To-day*, and also by a survey of the "University of London in War-Time, September 1939–March 1942", recently circulated in the Convocation of the University. Their part in reconstruction is no less vital. Both aspects of university war-time activity are reflected in two articles, which have appeared in a recent issue of *Science* (95, 369–72, 372–73 ; 1942), by Dr. Arthur Cutts Willard and Prof. A. J. Carlson respectively. Dr. Willard's address, "The University and the War", given at the Washington award dinner of the Western Society of Engineers, describes the ways in which the courses of the University of Illinois have been modified to meet professional demands for various services and its contribution to the war programme of the United States through the research activities of its scientific staff. The mere list of activities cited by Dr. Willard indicates that the University of Illinois is addressing itself to the immediate practical tasks of education, training and research, with vision and understanding. The contribution to morale of the Extension of Service in Agriculture and Home Economics, the trained specialists of which present to the people the results of scientific research carried out by the Agricultural Experiment Station, often in co-operation with the U.S. Department of Agriculture, is noteworthy, and the Engineering Science and Management Defense Training Programme is most impressive. Adult education, education in the armed forces and the encouragement of reading on the understanding of America, its aims, the War and the peace to follow are all represented.

Whereas the material contribution of the universities, of which London and Illinois are only examples, is important, the moral and spiritual contributions are even more important, and it is to this particularly that Prof. A. J. Carlson, of the University of Chicago, directs attention in his paper "The University and the Present Crisis". Emphasizing the particular dangers inherent to a university in time of war—which are involved in the very antithesis of education and war—he warns us of the importance of a re-examination of the relation of education and democracy before we attempt to modify educational institutions or systems in a period of hysteria and fear. There should be no relaxation in our standards of education, university or other. A period of war is not the best time for inaugurating basic educational reconstruction, though it is well to give timely consideration to the subject ; and a democracy should be specially on its guard against the dangers to education and to fundamental research which are always present in a war effort of the magnitude of that at present required.

From these comparatively negative obligations, Prof. Carlson turns to the positive obligations of the university at the present time. Among these he places foremost a tightening of the intellectual belt, a greater attention to duty for teachers and students. Waste of time must be rigorously eliminated, and both teachers and taught must recognize their responsibility for seeing that the golden hours are used to the full. The practical duties of placing university facilities at the disposal of the Government for training men in the special services of the armed forces, and for aiding in the solution of scientific and other problems forced on us by the War are put first, the training of the full quota required each year of medical men, physicists, chemists and engineers comes next, while finally Prof. Carlson stresses the importance of free minds, informed by principles derived from human experience through the ages, and open, no matter what waves of change beat upon them.

The duty and responsibility for aiding in the development and maturing of such creative and open minds lie mainly on the university, both in peace or in war. The universities are among the ultimate safeguards of freedom of thought, and to them we must look for the constructive criticism and imaginative insight essential in the elaboration of any sure plans for reconstruction when victory is won. The intellectual activities of the university, as President Hutchins writes, are the symbol of everything we have to defend, and the best service the university can render in the defence of the United Nations is to see to it that these activities are maintained in full force and vigour. Only the universities can carry the incredibly heavy burden of formulating, clarifying and vitalizing the ideas which should animate mankind; they must carry that burden, even in total war, if civilization is to be saved.

It is encouraging that the exceptional stimulus that the present struggle is undoubtedly giving to scientific thought is not leading the universities to overlook the great resurgence of social, economic, political, industrial and educational leadership which is required nationally and regionally. Possibly our Russian allies are prone to over-emphasize the material side of the university's contribution, as an article by Dr. P. Kapitza "Science and War" in *Science* (95, 396; 1942) suggests; but Dr. Kapitza also points out that the strain and tension due to war are exposing the weak spots in our economy, technique and organization, showing the points where the State must first be assisted, and clearly formulating the demands which society makes on science. In his speech in the House of Commons on June 16 on the estimates for his Department, Mr. Butler, president of the Board of Education, referred to the contribution to the war effort in the steady flow of qualified recruits for the specialized services, but it was clear that the importance of something more than academic qualifications for leadership was in his mind.

This was shown, for example, in the appointment of a committee, with Dr. McNair, vice-chancellor of the University of Liverpool as chairman, to investigate the recruitment of teachers from other academic services, as well as the question of the supply of teachers and of youth leaders. This and other steps already taken, such as the short courses for teachers in the history and current affairs of the United States and of the U.S.S.R., initiated in close co-operation with the American and Russian Ambassadors, and the establishment of a body under the chairmanship of Lord Fleming to work out a plan under which the facilities of a boarding-school education may be extended to those who desire to profit by them, irrespective of their means, while but indirectly connected with the universities, will facilitate the fulfilment of their task of supplying the nation with the trained leaders it requires.

The quality of the leaders which a university provides does not indeed depend solely upon the university itself. It depends partly at least upon the quality of the students entering on its courses, and therefore to some extent on educational systems of the schools. It is well to find, therefore, a new outlook on education reflected in the House of Commons debate, and such promising plans outlined in Mr. Butler's speech, though it should be remembered that much of the information required as a basis for decision has already been set before the Government by the Consultative Committee of the Board of Education with the aid of school inspectors. What is, in fact, required of the Government here is a definite plan for education, from the primary school to the university, upon which ultimate decision and action can be taken.

The real problem in a democratic society, in education as elsewhere, is to secure the full use of the nation's talents. The McNair Committee may be expected to advance proposals regarding the supply of teachers which will redress the lack of missionary zeal and first-rate competence; but this is only one direction in which the task is to open the door to men and women who can best serve by their boldness and ability, to give them opportunity in their public work and in their private lives to execute plans of action and to take responsibility. In the Civil Service adventurous spirits are lacking; in industry, vision and courage; in politics, honest, able men are scarce; and pride, enthusiasm and capacity are too often absent from the humblest to the highest spheres of work.

It is the function of the nation's schools and universities to provide the channels along which these men and women will pass. To make the schools themselves open to all equally, and at once uniformly well endowed in equipment and personnel and widely diverse in their freedom to develop, are essential steps to this end. Also it is essential that, simultaneously through the universities and by adult education, the nation should be brought to a new appreciation of the moral values upon which democracy is built and without which we look in vain for real leadership of youth or of any age.

If the schools and universities are to supply this creative leadership which is our first need, both alike must concern themselves with the preservation of moral standards and spiritual values. Too long have we allowed, as Lord Elton points out in his stimulating book "Saint George or the Dragon", the military virtues of loyalty, courage, endurance and discipline, upon which our very existence now depends, to be despised, ignoring the fact that they are the very basis of civilization itself; and punctuality, regularity and industry to be sneered at as slave values. Yet without these last even creative genius will never see the fruition of its gifts to man; and the first, though not the only Christian virtues, lie so close to the core of Christianity that we can scarcely wonder that twenty years campaign against them has led to a weakening in the hold of Christianity itself. Indeed, they can be reduced, as Lord Elton notes, to a single quality, unselfishness, and if there is one defect more than any other responsible for our unpreparedness for the present War, for the defects of the present social order, for the softness and love of ease and pleasure which may have led our foes to misjudge us but also earned their just scorn, it is the directly opposed vice of selfishness.

We may well be grateful to Lord Elton for his penetrating exposure of the shallow and misguided intellectualism which for twenty years has been so rampant against the virtues we need alike to win the War and to build the peace. Unless that lesson is learnt aright, there will indeed be no place to build. Civilization is self-discipline, and its advance is measured by man's gradual mastery of his more savage instincts. That much at least Nazism has revealed to us, and having once overthrown that menace it would be folly indeed to throw aside the moral values which have brought us to victory without making sure that we have found new and enduring values adequate to the spiritual as well as material tasks which lie ahead.

The extent to which the moral and intellectual foundations of civilization have been shaken is nowhere better revealed than in our lost capacity for moral indignation. The evil could, however, scarcely have gone so far had there not been a widespread indifference to the basic importance of character. From this the War has happily aroused us, and it has already been demonstrated that the nation possesses formidable reserves of courage, loyalty, fortitude and endurance, and that there is little lack of those willing to accept responsibility. It must, however, be the first concern of any kind of educational system to see that the emphasis on the training of character is never again omitted, from the university downwards. There must be no further betrayal, and the extent to which the conception of service is replacing that of private profit in the realm of industry and commerce must be reflected throughout that of education. That idea lies at the heart of the youth movement, but unless it is fortified continually by the teaching and example of the schools, the movement will never fulfil its promise.

In his stimulating chapter "Not Examinees, but Men", Lord Elton is writing primarily with the schools in mind, but what he says of them with regard to training in citizenship and the more effective choice of leaders is equally true of the university. The system of examination in book learning alone can no longer be retained. Means must be found of testing other qualifications for leadership besides the capacity to absorb and reproduce knowledge. Courage, common sense, originality of mind and sound physique—these also must be taken into account; and we should make sure that the educational ladder of the future is one to be climbed by boys who show signs of initiative and character as well as intelligence.

In the gearing of intelligence to character and experience, the retention of national service after the War may well play an important part. Conscription, whether in the fighting services or in the factories or on the land, might do much to toughen the physique, socialize the instincts and enrich the later learning in school or university. Moreover, by emphasizing the idea of obligations and services to the State from every citizen as the condition upon which its protection and privileges are enjoyed, it might do much to fortify the youth of the nation against the softness and heresies which the propaganda attacked by Lord Elton broadcast so disastrously between the wars.

The universities have a part to play here through the recognition of social studies. By a fuller and deeper appreciation of the importance of man as a vital entity in the structure of a dynamic civilization, they can lay the foundation for, or round off, as the case may be, the experience which a short period of national service can give.

No excellence in the material contribution of the universities in peace or in war can atone for any shortcomings in moral or spiritual leadership. It is not enough to recognize the shallowness and ineffectiveness of much of the intellectualism and scepticism of the last twenty-five years. Without idealism, without conviction, without a sense of the positive values of life, and a vision of those enduring spiritual verities of mankind, now imperilled, but by which alone man has made his slow advance out of the darkness and chaos of barbarism, there can be neither the moral passion which will overthrow the aggressor nor the balanced view of life which will enable a nobler and wiser civilization to emerge from the present turmoil. Man needs the inspiration of a living faith and an adequate working philosophy if he is to bring to the tasks that now confront us the serenity and the conviction that will bring them to success, and overthrow the forces making for social disintegration, whether in society, in industry or in international affairs.

The late Prof. J. L. Stocks said truly in his essay on the need for a social philosophy that our generation is not being given the tools necessary for a sound critical judgment in social affairs. Philosophy, he says, alone has the power to give them those tools. When men do not know the faith by which they live, they will be apt inadvertently to betray it. The universities are no longer academies of religion, though for centuries it was one of their main tasks to train the leaders of the Church. To them men may fairly look, not for the light of truth alone but also for the compelling force of moral conviction, for the enthusiasm which has a place in all genius and all creative work, and for the vision and wisdom by which men may steady their course and walk surely in this anxious, crumbling world.

The universities fail of their full purpose unless they give to their alumni in some measure the power to see life steadily and to see it whole, and the capacity to re-discover and re-create for each fresh generation truth in all its many facets which, as Dr. R. R. Marett reminds us, can never afford to stand still. With courage, loyalty, discipline and endurance, a civilization may be strong to defend itself, but without also culture and religion it is unworthy and indeed unable to survive.

Here then is the point at which the universities must face anew the interpretation of religious experience and of the spiritual heritage of mankind. Their responsibility to-day for imparting to all their students and scholars some sense of the scientific outlook and spirit, with its untiring passion for truth, the ceaseless testing and sifting of the accumulated knowledge of mankind as part of the discipline which equips men and women alike for life and leadership in this modern world, is admitted. There must now be recognized also their responsibility for instilling as a counterpart to legitimate scientific scepticism a respect for the accumulated wisdom of mankind, and a training in cultural and ethical values which will lead to the formation of sound judgment.

To leave the young, in the sphere of wisdom, to re-discover painfully for themselves the moral and spiritual truths which the accumulated experience of past generations has accepted as making for the good life in the individual and in the State is neither science nor sense. In the sphere of knowledge, the scientific worker does not hesitate in practice to accept the conclusions of the past, or to stand upon the shoulders of his predecessors. Both in knowledge and in the realm of wisdom, to reject all the observations and experience of the past and to insist on verifying afresh every single fact or technique leads at once to chaos and deadlock, not to progress.

It is this task of cherishing the rich moral and spiritual heritage of mankind and stimulating the creative thought which will lead to the discovery and formulation afresh of a faith and a philosophy adequate to meet the challenge of to-day that is the supreme responsibility of the universities. They, as none other, can build up the aristocracy of ability and integrity which Zinsser insisted is essential to maintain a democracy and protect it from deterioration and eventual chaos. If science and religion are to found a fellowship which will lead men forward, facing change in the spirit of science, trending upward in the way which religion alone in the elements of human experience, as Whitehead points out, has consistently done, the universities will assuredly prove a decisive factor. Only as they play their full part can those bright hopes of the youth movement or the vision of service, of sacrifice and adventure dawning anew on the minds of men and women in so many scattered walks of life, find their fulfilment in action and in a fellowship strong and serene enough never to be turned again by selfishness or love of ease from the task of building a nobler world order and adding, in response to the call of prophetic statesmanship, their own contribution to their heritage of culture, learning and religious experience.

THE ANATOMY OF FREEDOM

Freedom: its Meaning

By Benedetto Croce, Charles A. Beard, Jacques Maritain, Bertrand Russell, Gaetano Salvemini, Vilhjalmur Stefansson, Henry A. Wallace, Henri Bergson, Alfred North Whitehead, Thomas Mann, Felix Bernstein, Harold J. Laski, John Macmurray, Albert Einstein, J. B. S. Haldane, Lancelot Hogben, Frank Kingdon, Franz Boas, John Dewey. Planned and edited by Ruth Nanda Anshen. Pp. vii+335. (London: George Allen and Unwin, Ltd., 1942.) 16*s*. net.

A VARIED assortment of essays make up this book. Though it is certainly useful to have these different points of view and different subjects brought together for comparison, the method has disadvantages. The essays are arranged in alphabetical order of the authors' names, an arrangement more convenient for the editor than the reader. Three of the essays (those by Bergson and Profs. J. Dewey and A. N. Whitehead) are chapters taken from published books, and it is possible that their original context suited them better. There is a serious gap in the ground covered: namely, no more than incidental references to the legal aspect of freedom. Prof. H. J. Laski could have done this very well, but he has preferred to discuss the problem of nationalism as an obstacle to freedom. If only each writer, before finally committing himself, could have read a preliminary draft of the other contributions, it would have been an improvement. For example, it would have saved Dr. V. Stefansson 'flogging a dead horse' if he had read the explanation by his fellow anthropologist, Prof. Boas, that primitive man lacks the concept of freedom. Unfortunately, this last suggestion is a counsel of perfection. Only a superhuman editor could cope with such conditions.

Despite these defects, the editor's claim to have reached a synthesis is more nearly realized than one would have thought possible before reading the book. Present-day facts speak too clearly to be ignored. We can all see, to quote Benedetto Croce, "the barrenness in terms of thought, science, art, civic virtues, human relations, that systems based on violence—or on what amounts to the same thing, on authority—commonly show. Everything sound and productive that still survives, or flourishes in them in the directions mentioned, survives and flourishes either through the survival of free minds or through the persistence of acquired habits. But these latter gradually weaken for lack of sustenance and replenishment and through the passing of the human beings who possess them. Meanwhile none of the new formulas or ideals is allowed to defend itself in orderly discussion, to justify itself by critically tested arguments, by interpretations of history, in a word by perspicacious, cautious, sober research. It is forced to drone its arid mechanical assertions over and over again, without variations, without proofs, without elaborations, deriving such animation as it can from an accompaniment of threats" (p. 57). The intellectual equipment we need as defenders of freedom is to understand the nature of social and political freedom, the historical circumstances that have favoured its development, how much we have of it now, and what is necessary for its preservation and extension. These are the topics discussed in this book.

There is a widespread and dangerous belief that the obstacles to freedom are incidental difficulties asily put right by some simple change in State rganization. As Prof. J. Macmurray provides a uch-needed corrective, his essay is worth condering specially, even if it means neglecting other xcellent contributions. Freedom, he says, "as we xperience it resides in the adequacy to our purposes our powers, opportunities and means" (p. 178). onstraint, its opposite, is of various kinds but the nly one of importance is that imposed by the clash human wills. When something that is otherwise ossible is rendered unattainable by the opposition f another person, it is felt and resented as oppression. hile increase of scientific knowledge has rendered any things possible which in the past were objecvely impossible, human relations have been such at many possibilities have not been realized. Thus crease in power has meant actual diminution of eedom. The main source of trouble is that human lations are of two sorts, depending on the kind of otives involved. If two men are partners in business, e important fact about the partnership is its rpose. If the purpose is accomplished or found to unattainable, there is no reason for that partnerip to continue, as it is only a means to an external d. The success of the partnership depends only ghtly upon any personal affection or animosity the rtners feel for one another. Indeed it is not necesry for them to meet or know each other or comunicate except on business. This kind of relationip is the sphere of economics and politics, and gives e to 'society'. But if two men are friends the lationship is quite different. Though they may ve a common purpose and be partners in business, is pointless to ask what is the purpose of the iendship. This is the kind of relationship that gives e to 'community'.

"In the nexus of personal relationship community capable of generating and containing society within elf, of making co-operation for the achievement of mmon ends a means to itself and an expression of elf. Therefore it is clear that if the problem of mmunity is solved the problem of society will be ll on the way to solution" (p. 188). Society, on e other hand, can exist quite independent of comunity. It is also more permanent and powerful. As rsonal affections and animosities hamper rather an promote social organization, society is apt to mand from its members loyalty to common ends erruling private ends. It also tends to treat its mbers as means only. Struggles for freedom have en mainly attempts to change the organization of iety, with disappointing results for the most part. of. Macmurray concludes pessimistically that there no technique of freedom. In other words, liberty d equality are empty forms without fraternity, and ere are no rules for achieving this.

There is no doubt Prof. Macmurray is right in ying that by itself society can generate tyranny t not freedom. Still, it is possible that his pessimism s too far. He may be looking too exclusively at debit side of society and the credit side of commity. Granted that love and affection are the basis community, it was these that produced the blood d. There has been no greater single human ievement than that by which an act of violence, ich was once a private wrong to be avenged on family of the agent by the family of the sufferer, become a breach of the King's peace. This is the ans by which we are free to walk abroad unarmed, leave our doors unlocked and to sleep in our beds hout fear (except for acts of the King's enemies). Society has stepped in to prevent community destroying itself. An even greater attempt, never completely realized, is the Roman notion of the equality of all before the law, in place of one rule for ourselves and our friends and another for outsiders. Law is the only final safeguard of freedom, but it does not work automatically; it needs active support and criticism, such as society cannot produce. Prof. Salvemini rightly emphasizes the democratic virtue of humility, because humility is needed for tolerance. But this is one thing the democrat cannot tolerate, so that he needs the contrasted virtue of vigilant sympathy that will not stand by and see injustice done.

A. D. Ritchie.

THE LABORATORY MOUSE

Biology of the Laboratory Mouse

By the Staff of the Roscoe B. Jackson Memorial Laboratory. Edited by George D. Snell. With a chapter on Infectious Diseases of Mice, by J. H. Dingle. Pp. ix+497. (Philadelphia: The Blakiston Company, 1941.) 7 dollars.

The Roscoe B. Jackson Memorial Laboratory in Bar Harbor, Maine, celebrated its tenth anniversary in 1939. During this short space of time, the staff of the laboratory, under the leadership of Dr. C. C. Little, in addition to numerous important investigations, has carried out a task which puts large sections of medical research deeply in their debt. The primary object of the laboratory is cancer research; Dr. Little and his team realized very early that many phases of this problem cannot be tackled successfully without bringing the genetic variables under control. A homogeneous strain of animals can be produced by continued close inbreeding. But a single pure line would be of very limited value; so the laboratory set out to establish a large number of inbred strains of mice differing widely both in the incidence of tumours and in the type of malignancy to which they are prone. But this 'variety of uniformity', unique in mammals, is also an almost untapped source of material for the study of innate and environmental factors in nearly any conceivable phase of mammalian biology and pathology. It would be difficult to muster a more competent team to write a biology of the mouse than the staff of the Jackson Laboratory.

The book under review brings together most of the scattered information on the mouse as a laboratory animal and contains more than 1,100 references. But it is more than a compilation. Some of the sections are based on research specially undertaken to fill in gaps in our knowledge, and unpublished data on many subjects are scattered throughout the work. The book opens with a clear and well-illustrated section on early embryology (54 pp.) by G. D. Snell, followed by a chapter on reproduction (33 pp.) by the same author. Histology (79 pp.) is treated by E. Fekete with numerous excellent photomicrographs. Beautifully illustrated is also the section on spontaneous neoplasms (66 pp.) by A. M. Cloudman, which is followed by a short account (14 pp.) on gene and chromosome mutations by G. D. Snell. Dr. C. C. Little contributes chapters on the genetics of spontaneous tumour formation (31 pp.) and of tumour transplantation (31 pp.) respectively; neither of these sections is exhaustive, but it was probably a wise decision to abstain from monographic treatment of a subject so much in flux. Short sections on endocrines and tumour formation (11 pp., G. W. Woolley) and the "milk-influence" in tumour formation by its discoverer, J. J. Bittner (4 pp.), are followed by a useful discussion on the value of inbred and hybrid animals in research (W. L. Russell, 24 pp.), which is addressed to the non-geneticist and should go far to clear up common misunderstandings. Parasites are treated by W. E. Heston (31 pp.) and infectious diseases very extensively (95 pp.) by J. H. Dingle, of the Harvard Medical School. A short section on care and breeding (J. J. Bittner, 5 pp.) and an adequate index conclude the book.

The contributions are generally well written and excellently illustrated. It will be indispensable to all workers who use the mouse as an experimental animal, and to students of cancer in particular. I have noticed only two slight errors. The root of the upper incisor does not reach so far back as the molar region (p. 110), and the gene for hypotrichosis juvenilis does not overlap normal (p. 241). HANS GRÜNEBERG.

NEW CYTOLOGICAL TECHNIQUE

The Handling of Chromosomes

By C. D. Darlington and L. F. La Cour. Pp. 166+16 plates. (London: George Allen and Unwin, Ltd., 1942.) 8*s*. 6*d*. net.

THE study of chromosomes is a branch of biology which has expanded very considerably in the last fifty years and has recently acquired an extended popularity owing partly to its association with genetics and partly to an increased technical facility which has been gradually built up from the accumulated experience of many workers. The modern microscope, perfected at the end of the last century, and the use of the microtome were understood before the War of 1914–18 and have not been improved appreciably since. On the other hand the last twenty-five years have added the smear techniques associated with the use of rapid and transparent (but often transient) stains, which can also be applied to extend the use of the microtome to very thick sections. Some improvements have been made in the formulæ of fixatives and, for certain purposes, by using reagents such as acetocarmine and rapid macerating treatments involving hydrolysis with hydrochloric acid, it is now possible to see in a few minutes things which a generation ago would have necessitated a delay of several days. In other cases whole fields of new observation have been opened up by the development of special methods such as those now available for the demonstration of spiral structure. The most recent innovation, and one which is certain to be further extended in the future, is the application of specific chemical reactions such as selective digestibility and microchemical colour tests such as Feulgen's reaction to the study of chromosome structure.

In an expanding science, some guide to new technical advances is needed from time to time and the part which Darlington and La Cour's little book could fill is obvious. Whether it in fact does so is less certain. Much useful information is undoubtedly contained regarding new methods, some of which are indeed published here for the first time. For this the cytological specialist will be grateful though he may perhaps resent some sweeping generalizations and a tendency to over-simplify, for example, the labelling of Caspersson and Hillary's lanthanum acetate trypsin method as "precipitation and digestio of nucleic acid" (p. 57), when the essence of it precipitation of nucleic acid and digestion of protei

The book is, however, not primarily addresse to cytologists but to "teachers and students in scho and university". Presumably for their benefit spa has been given to elementary instructions on how write a paper (Chap. 12) and to drawings of comm utensils such as slides and staining jars (pp. 126–7 The uninformed reader would, however, go away wi the impression that all cytology is very new ar very easy and that he need know little or nothi about information available before about 1920. Th appears to the present reviewer to be a great mistak The modern developments amplify, but do not any means eliminate, the usefulness of the old achievements. Sound microscopy is still the keyno of successful cytology and a student can profit ve greatly by learning to use old equipment such as t paraffin oil microscope lamp, and by careful perus of an old and classic handbook on the microsco such as that of W. H. Carpenter (eighth edition, 190 still available in most reference libraries). It doubtful whether he could acquire even the minimu of necessary information on the use of the microsco for high powers from the very brief and somewh peculiar paragraphs devoted to it in the book und review; though he might easily be confused references to the numerical apertures of lenses a condensers, made without explanation of the ter and to discussion of the relative merits of differe resolving powers when these are expressed mere as microns (p. 24).

It is difficult to see what class of reader cou benefit by perusal of the chapter on photograph and the price of the book has certainly been enhanc by the inclusion of large photographic illustratio using magnifications up to ×10,000 although it physically impossible, with visual light, to obta any image of detail finer than will reproduce in ha tone at a magnification of ×3,000, and for scienti (as opposed to artistic) purposes even this degree enlargement is generally excessive. The difficul of using an old (and valuable) stain such as hæm toxylin is stressed but it is trivial in comparison wi that of applying polarized light to chromosom problems, yet a student would receive exactly t contrary impression from the descriptions given the property investigated by the latter method incidentally, not "rotation of polarized light" (p. but birefringence, that is, the property which a chrom some may or may not possess of splitting a beam polarized light into two beams polarized at right ang

It is not difficult and it is sometimes desirable cut sections thinner than $14\,\mu$, but a student's troub would be magnified by making him use only extremely hard wax of m.p. 58° C. for such a purp (p. 48), for, in temperate climates, almost all cy logical material, in plants at any rate, will cut sa factorily in m.p. 52–54° C. at thicknesses of 6–1 and extra hardness is only needed for exceptio specimens or for thicknesses of $4\,\mu$ or less.

To meet adequately the requirements of a stud or inexperienced teacher, much greater care wo need to be expended on the accuracy and bala of the matter to be presented. For a more experien reader, on the other hand, much will be redund and emendation of details will be necessary, bu solid core of real value remains if the book is trea as a source of introductory reference to some teresting, new and useful laboratory methods.

e more precise, it is worth buying for the sake of me of the notes contained in the appendixes and r some of the information summarized in the apters dealing with the making of smears and uashes, with the handling of special tissues such as ollen tubes, embryo sacs and salivary glands, and ith the application of special agents such as X-rays, rugs and the various treatments for spiral structure.

I. MANTON.

PRECOLOMBIAN HAITI

xcavations in the Ft. Liberté Region, Haiti

y Froelich G. Rainey

ulture of the Ft. Liberté Region, Haiti

y Irving Rouse

Yale University Publications in Anthropology, Nos. 3 and 24.) Pp. 48+196+35 plates. (New Haven, onn.: Yale University Press; London: Oxford niversity Press, 1941.) 21*s*. 6*d*. net.

THESE two papers, issued as a single volume, give an account of the culture of a small area n the north-east corner of the Republic of Haiti, nd of the excavations on which it is based. With ne exception, the sites lie within an area measuring bout 7 km. by 5 km., and the remaining site is bout 10 km. farther east.

The first paper is an admirably concise account of he excavations by Dr. F. G. Rainey. Eleven sites ere investigated, all of them shell middens. Five f these yielded a culture characterized by flint nplements without pottery, burials or defined earths; the remainder, which were somewhat rger and thicker, though the maximum thickness f deposit was only about 1·5 metres, contained ottery. Of these, four were assigned on the basis of eir pottery type to one culture, called the Meillac, nd the other two to another, with a different type f pottery, called the Carrier. A few primary burials ere found in the middens on Meillac sites: they ere in poor condition, but appear to have been in flexed position, and in two cases were accompanied y pots. No other grave goods were found. There as also evidence of secondary burial. There was o stratification which threw light on the relative ges of the cultures on any of the sites, but a small dmixture of Carrier pottery was found on three of he Meillac sites.

The paper is illustrated by two maps, both of hich have been reduced too much, a criticism which pplies particularly to that of the Ft. Liberté Region, hich also lacks a scale. The remaining figures are lans and sections of the sites. These are perfectly lear, but the vertical scale has been exaggerated as uch as ten times in several cases and forty in one. Where possible, it is better to draw sections true to ale: the amounts of exaggeration cited are in any vent excessive.

The second, much longer, paper, by Dr. I. Rouse, an account of the cultures. He classifies them into ur periods. The first, comprising Rainey's flint tes, is occupied by the Couri Culture. Period 2 is blank separating the Couri from the Meillac Culture, nd no evidence for its existence is presented. Preumably it is based on the absence of any admixture Meillac objects on Couri sites, but this is not an dication of any value when the small size of the ea studied is considered. Period 3, with its four tes of the Meillac Culture, is divided into four subivisions. The evidence for this appears to have been presented in a previous paper by the same author, but the value of these minor periods is on the face of it extremely dubious. Period 4 comprises the two sites of the Carrier Culture.

There is no reason to doubt that the Couri Culture is the earliest, but the question of the relative ages of the other two is more difficult and may not yet be finally settled. The author says that he demonstrated the greater age of the Meillac Group in his previous paper "by distributional and statistical methods", but their merits cannot be judged since the paper is not available. He believes that the Carrier type of pottery originated in the Dominican Republic when the Meillac type existed in the Ft. Liberté region, and that the Carrier type, which is the more sophisticated, replaced the other by diffusion. It seems likely that this explanation is correct.

Dr. Rouse's account of these cultures could scarcely be fuller, but it is difficult to read and excessively long owing to his method of presentation. He is trying to introduce a definite procedure for classifying culture and in doing so he uses a lot of terms which are not likely to command wide acceptance. In his desire to apply his system throughout the work he involves himself in much unnecessary repetition and many glimpses of the obvious. The term 'mode' lends itself particularly to this sort of thing. Absurd 'modes' are legion, but one list must suffice as an example. After a detailed description of the petaloid stone celts (in the course of which we are told that they are relatively heavy, rigid and hard !), we find the following conclusions on p. 95: "The following are the modes for petaloid stone celts: igneous rock, metamorphic rock, dullness of the rock, bright greenness of the rock, flaking (?), battering (?), grinding, polishing, resharpening, high surface polish, petaloid shape, pointed butt, convex sides, convex edges, semicircular bit, large size, small size, use for chopping, and ceremonial use. . . ." The conceptions of "alternative" and "optional" modes do not seem to clarify the descriptions, and it is difficult to see what purpose is served by the numerous tables giving "alternative and optional relationships of the modes", etc., particularly when they contain column headings like the following: "No overall shape", "No body", "No aperture", in a table dealing with open bowls. They appear to represent an abortive attempt to reduce classification to a mathematical basis, and they would have been better omitted.

Appendix I consists of a detailed report by specialists on a technological analysis of Meillac and Carrier sherds, in the course of which they state definitely that there is no evidence of artificial tempering. In spite of this, the author discusses the whole question afresh on p. 55 and suggests the same conclusion as "mere conjecture".

The plates consist of excellent photographs of the objects, of which there are plenty of examples. There are, however, several numerical mistakes in the references to them in the text.

The final chapter is an attempt to relate the cultures to others in the West Indies. It contains thirteen pages, of which more than seven are occupied by tables, most of which do not add any useful information to the work. The result of it all is to show that the Meillac and Carrier Cultures have been proved to exist elsewhere in Haiti, but that it is premature to try to correlate them with anything farther afield, a fact which is clearly demonstrated by the high proportion of space occupied by queries in the final table.

G. H. S. BUSHNELL

THE VALUES OF SCIENCE TO HUMANITY*

By PROF. A. G. TANSLEY, F.R.S.

TO most people to-day the word science suggests, first of all, the marvellous modern applications of science to human use. Such inventions, yearly increasing in numbers and in scope, have enriched human life not only on its material side, but also indirectly, in æsthetic, intellectual and spiritual aspects. By quickening every sort of intercommunication they have put the most widely separated products of human thought and creativeness at the disposal of everyone. By 'annihilating time and space', as the vivid phrase goes, they have drawn the peoples of the world together.

It is tragically true, of course, that scientific inventions have also placed enormous means at the disposal of those men of evil will who have seized power in their own countries and have taken advantage of the deficiencies of international organization to disrupt and overwhelm neighbouring States. Shallow and thoughtless critics have blamed science and men of science for these catastrophes. They should rather have blamed man's failure to develop an adequate ethical standard in international relations, his failure to acquire that sense of human solidarity with which the race can no longer dispense if it is to survive under tolerable conditions. Not science but lack of morality is the culprit. Man's material power has altogether outrun his ethical development. It is as impossible to check scientific discovery and its application to human purposes as to stop an inflowing tide. What those purposes shall be must depend on the degree of man's spiritual development, on the values in which he really believes.

The primary motive that prompts a man to learn and practise science is the desire to obtain organized knowledge of the objective world around him. Such knowledge may be sought for its own sake or for its practical usefulness. When the former motive is predominant we have been accustomed to speak of 'pure science', as contrasted with 'applied science' when scientific knowledge and scientific method are used for the solution of practical problems of human life. The devising, improvement and elaboration of technical methods of dealing with materials and processes for practical ends may best be called 'technology'. But we are told by an increasingly vocal school of scientists turned publicists that there is no real distinction between pure science and technology, that the root of man's interest in knowledge of the natural world is the use he can make of it, and that pure science is either the theoretical formulation of knowledge originally sought for purely practical ends or, when it is not this, a form of recreation which is at best harmless if it does not divert attention from more serious and useful pursuits.

The essence of science is said to be the acquirement of power over Nature. Science has been actually defined as "the system of behaviour by which man acquires mastery of his environment". We had supposed, until we were thus instructed, that science meant a kind of knowledge, not a kind of behaviour. Indeed the most elementary thinking about the human mind and human activity would seem to require a primary distinction between knowing an behaving.

But if we pass over this extraordinary misuse o ordinary language we are confronted with two contradictory views of the status and function of scienc —on one side the view that science is a body c knowledge primarily concerned with the effort t satisfy human needs, 'pure' science, so far as it ma be entitled to recognition at all, being an offshoot so to speak, of this body of knowledge; and, on th other hand, the view that pure science is a primar body of knowledge and theory, which has no necessary relation to practical needs, but much of whic may be applied to those needs with far-reachin effects. What is the explanation of this contradiction I think it may be found in the confusion of historica and psychological points of view. Historically, pur science may fairly be said to 'emerge from' a bod of knowledge much of which is empirical and technological. Psychologically, pure science, as it exist to-day, has a completely independent status, an incidentally is the source of all significant technological advance. Let us consider this matter in som little detail.

That the kind of knowledge we call science lead directly to increased power over Nature, that it i the source of our wide and powerful modern contro over the materials and forces of the external world is obvious to all. Primitive man got the first glimmerings of the foundation of scientific knowledge—that similar causes produce similar effects—in th conditions of his hard daily struggle to maintai himself and perpetuate his race in a hostile or a best an indifferent world. Such knowledge was purel empirical knowledge. Fire burns, but it will als cook food and scare off wild beasts; water drowns but it also quenches thirst; sharp flints can be use as weapons and also as tools, and so on. Empirica knowledge is not science though it is the indispensabl basis of science. A good many writers are in th habit of using the words 'science' and 'scientific' fo *all* knowledge gained by primitive man, and in th earlier civilizations, about his material environment simply because it related to the objects and processe which now form the subject-matter of branches o science such as physics, chemistry, geology an biology. Most of this knowledge was purely empirica Science does not come into existence until some kin of generalization is formed in the mind, a generalization that can prove its validity when it is applied t new phenomena.

The transition from purely empirical knowledge t the first rudiments of scientific knowledge was n doubt an imperceptible transition. We do not kno and can never know the times and places and way in which the first ideas which can properly be calle scientific arose out of the bodies of empirical knowledge. We shall be safe in giving the first place t the general notion of causation, an essentially abstrac conception which underlies all the rest. The causa nexus between happenings could not fail to impres itself on the primitive human being experiencing th events of his daily life. That *B* happened *because* had happened must have been a very early thought

There is no evidence and no likelihood that th basic mental equipment of primitive man—at leas of men of our own species from Upper Palæolithi times—was substantially different from our own but he was without our *heritage* of knowledge. H had to begin from the beginning, from the platform of adaptive instincts built up by and inherited fro his sub-human ancestors. But he had in supreme degree the power of adaptation and intelligent modification of those instincts to new conditions of life, and with the acquirement of the power of articulate speech he could initiate an oral tradition of knowledge. Thus bodies of traditional knowledge were established, handed on, and gradually increased from generation to generation, varying according to the different environments in which different human groups found themselves. These bodies of empirical knowledge necessarily related primarily to the vital needs of the group, and so it has been throughout the hundreds of millennia of man's history. Equally in pre-glacial times, when man first began to emerge from among his ape-like ancestors and in our twentieth century of the Christian era, equally in London and in Timbuktu, the individual *must* acquire the knowledge immediately necessary to his continued existence, however widely different the content of that knowledge may be.

---

* Extracts from the Herbert Spencer Lecture delivered in the University of Oxford on June 2, 1942. The complete lecture is published by George Allen and Unwin, Ltd., 1*s*. 6*d*. net.

So it is also with the aggregate knowledge of a particular human group or community. Those communities which had acquired the particular type and degree of knowledge and skill best adapted to their particular environment were the most likely to survive; and when they came into competition or open conflict with others, those communities would win whose knowledge, skill and material equipment best fitted them for success in the struggle, because the environment of each community included the incidence of its competitors.

How far did primitive man seek objective knowledge of Nature for its own sake, besides acquiring the knowledge essential to his existence? That, of course, we can never know with any approach to certainty. But it is significant that unspoiled savages to-day show at least as much interest in natural phenomena which do not affect their material interests as does the man in the street of a community which is called civilized. Since curiosity is certainly a primitive human instinct, and it leads to the acquirement of knowledge which is independent of practical usefulness, we can scarcely doubt that such knowledge was sought from a very early period of human history. But pure science cannot attain any considerable development in a society with little leisure. Where the conditions of life are so hard that everyone is almost wholly occupied in keeping body and soul together there is no time or mental energy available for the acquirement and organization of much knowledge for its own sake. In such conditions the great bulk of the knowledge that is acquired is practical knowledge, how to secure and extend control over that part of the environment which is of immediate practical significance, and then to make life easier and more comfortable. Thus arose the arts of food-gathering, of hunting and fishing, of stone implement making, of the taming and training of animals, of primitive agriculture, of weaving and pottery making, of building and primitive metallurgy. Chance observations, hit and miss experiments, the use of experience and primitive inductions, must have been the means employed. The improvement and elaboration of these various arts were the foundations of technology.

With the attainment of settled conditions and the advancement of technology, surplus wealth, that is, stocks of commodities not required for immediate use or consumption, could be accumulated, trade could develop, comfort could be increased, and eventually the luxury created which has been so marked a feature of the more elaborate civilizations. At the same time leisure became more abundant, at least for some members of the community. The arts of writing and of calculation were invented, and geometry and astronomy began to emerge as coherent bodies of knowledge. Practical needs such as trade, craftsmanship and the making of calendars were no doubt the immediate stimuli to these developments; but since we have every reason to believe that the mental constitution of the races which have occupied the Near East and Europe during the last four thousand years has been essentially constant throughout, it is impossible to doubt that the satisfaction in discovering new knowledge for its own sake, which is the driving force of research in pure science, must have been present in those early civilizations of the great river valleys of the Near and Middle East just as it was probably present in much earlier savage ancestors.

From at least the sixteenth or seventeenth century onwards there has been a body of scientific knowledge and theory which had *continuity*, and each generation could build upon the foundations laid by its predecessors. Discovery in science, hitherto isolated and sporadic, became a continuous process, and thus pure science, cultivated for its own sake, acquired an independent life. Needless to say, it was often influenced in volume and direction by social and economic as well as by intellectual conditions, and it often took technical problems as starting-points. But it was never wholly determined by such influences, and a great deal of it was undertaken with no reference whatever to the usefulness of its results. It is such research, in fact, that has ultimately led to the most striking practical discoveries and inventions. It is a striking fact that many discoveries made in the course of work undertaken with no practical aims have unexpectedly turned out to be keys to important applications of science in wholly different spheres. As scientific knowledge and theory become increasingly complex all sorts of cross-connexions between different departments reveal themselves, new branches arise, occupying hitherto unexplored ground between the older fields, and others cut across the old boundaries and take their material from several such fields. For this reason alone—the unexpectedness of discoveries and the unexpectedness of their applications—it would be disastrous to attempt the direction of all research to specific practical objects or to hamper complete freedom of investigation.

At the same time we must recognize that a good deal of work in pure science is unlikely ever to be of any practical use, though it may be of the greatest interest. Such, for example, is the detailed *history* of the earth, of its rocks, its vegetation and its animal life, and also a great deal of the detailed morphology of the plant and animal kingdoms. Should we discourage such work or deny it the necessary facilities? There are at least two good reasons why we should do nothing of the kind. In the first place we could never safely draw the line between work which might prove materially useful and work which certainly never would. If we once began to draw such distinctions we should put science into the power of those who clamour for results of immediate practical use and have no understanding of the complex and vital inter-relations of its different parts. The second reason goes much deeper, though it is connected with the first. Any such restriction of research would deny the right of men of science to investigate and increase our knowledge of the *whole* phenomenal world, and the right of the individual man of science to choose the field which his abilities and inclinations best fit him to explore.

The immense and complex development of pure science has the most far-reaching applications to human activity and profound effects on technology. Separating out, as we have seen, from the undifferentiated body of scientific discovery and technological invention of a former age, and acquiring an independent life of its own, pure science became the main source of all fundamental technological advance, while its full potentialities of application to other fields of human life are just beginning to be realized.

Historically, then, scientific theory arose piecemeal in one field and another, emerging from the growing structure of practical empirical knowledge or from the independent study of Nature. Gradually the separate pieces coalesced and began to form coherent bodies of theoretical knowledge. As it became securely established the structure of scientific theory acquired an independent existence and its description as 'pure science' became justified. On every hand it fertilized technology and made possible great advances and entirely new developments in the most various technological fields. Thus the term 'applied science' began to be used for the applications of pure science to the practical purposes of human life. Once established as an independent human activity, pure science assumed a continuity and a universal status which technology can never have, simply because all but the most elementary material human needs are partial and variable, so that human arts and crafts and manufactures rise and fall, appear and disappear, while organized knowledge of the world of Nature is permanent and free from such fluctuating conditions.

Technology is essentially 'patchy': technological research is occupied in solving unrelated practical problems of technique in the most various fields of human activity. Deeper penetration to underlying causes is not, as a rule, any concern of the technologist. All he cares about, as a technologist, is the solution of his immediate problem. The pure scientist, on the other hand, is perpetually seeking underlying causes, relations between things previously unsuspected of being related. This constant search is the essence of pure science, and when it succeeds great new fields are often opened up for exploitation by the technologist.

Recent writers who have envisaged not only technological but all scientific work as a 'social activity' determined by current social conditions and directed to the satisfaction of current social needs, have had no difficulty in demonstrating the general correlation of work that may be described as scientific with social structure and social requirements at various times and places. But to justify their sweeping conclusions they have had to lump together the whole body of empirical, technological and pure scientific knowledge of Nature and of human arts and crafts acquired throughout the ages; and they have misrepresented with a strange perversity the real nature and the essential psychology of scientific research. Up to the seventeenth century research for the sake of pure knowledge was on the whole sporadic, and the great bulk of the work described as determined by social conditions was technological work, though great scientific discoveries and generalizations were made here and there. Since then, as pure scientific work began to coalesce and acquire continuity, the determination of its direction by purely social factors has become less and less marked.

Leaving now the historical development of science we turn to the essential psychology of scientific work of various kinds.

No one contends that scientific men who engage in research are entirely uninfluenced by the social conditions of their time or by the particular conditions of their own early life and environment. It is obvious enough that these conditions must have a great effect on the formation of the scientist's mind and therefore on all his activities. The individual human mind has a certain specific hereditary endowment, but it does not work *in vacuo*. The material with which it is fed in childhood and youth and the influence of its particular environment must play a large part in determining its future activity.

The actual motives, both conscious and unconscious, which may cause a man to-day to embrace a scientific career of any sort are various and of different orders; the same, of course, may be said of any other human activity. For the vast majority there is the over-riding necessity of earning a living, and the particular work or career adopted will obviously depend on opportunities and prospects. A century ago a 'career' in science was open only to a very few. To-day opportunities are numerous and increasing, owing partly to the rapid growth and development of pure science but mainly to the enormous extensions of applied science and technology. The great majority of these openings lead only to laboratory posts the duties of which are those of what is sometimes called 'routine research', that is, to the making of tests, trials and checks on the instructions of a superior. A smaller but still a considerable number of posts are available in teams of research workers in industrial or Government laboratories engaged on the attempted solution of technical problems or sometimes of problems in pure science which are thought to have a direct or at least an indirect bearing on technical progress. This again is 'directed' work, just as much as that of a clerk in an office, though its intrinsic interest to the scientifically minded may well be much greater. To a few comes the possibility of promotion to the position of a subordinate director of the technical work of others or to the headship of a research team, and a very few may become directors of scientific departments or institutions where they will have much more opportunity of initiative, though very commonly such appointments are not made from the personnel of the particular laboratory, but often go to people from outside with a different sort of training. It is obvious, then, that to the vast majority of 'scientific workers' only technological work in which there is little freedom or opportunity for initiative is available.

There remains the possibility of employment in the teaching of science as a schoolmaster or at a university. A few schoolmasters find time and inclination for independent research, but the conditions are not often favourable. On the other hand, academic science teaching is usually combined with research and most of the current research in pure science is actually done at universities, much of it by university teachers.

Probably most of those who adopt one or other of these scientific careers—certainly those who enter the last-named—in order to earn a living have to a greater or lesser degree what is called the 'scientific bent'. This shows itself either as a strong interest in and desire to obtain organized knowledge of the natural environment—more often of some particular part of it, such as stars, rocks, animals, or plants—or as a specific interest in 'how things work' commonly seen in a small boy's keenness to find out how a machine is constructed and how its parts act.

What are the psychological factors underlying the 'scientific bent'? 'Curiosity' is the most general concept under which the first impulse to both kinds of scientific interest—in environment and in working mechanism—may be brought. Curiosity has been defined as "the desire or inclination to learn or know about anything, especially what is novel or strange". This is the adult expression of the curiosity which may fairly be regarded as a primary instinct of many higher animals, and is conspicuously displayed by human beings from a very early age. The human infant expresses it by making sensory contacts with the unfamiliar objects of its immediate environment, through sight, smell, taste, touch and manipulation. This is the primitive means of 'getting into touch with' or acquiring knowledge of one's surroundings.

The promiscuous curiosity of the young child, if it is not smothered by overwhelming repression but is controlled and canalized by the direction of intelligence, under the influence of growing experience, develops into the desire for organized knowledge of the objective world around him. This may take either or both of the two forms we have already distinguished, leading to interest in the 'natural history' sciences or in what has been called "general analytical science". Much can be learned from books and from oral teaching, but the unblunted instinct can be directly satisfied only by independent observation and experiment. It is the satisfaction by talented people of the desire for organized knowledge of the objective world that has gradually built up the permanent structure of pure science by successive descriptions and discoveries and by the conceptual welding of these into coherent bodies of scientific theory, the parts of which are constantly modified or replaced as fresh discoveries are made or deeper insight gained into the relations of phenomena.

The consistent object of pure scientific research is to establish a coherent body of objective knowledge and explanatory theory over the whole range of natural phenomena. In the course of this work new phenomena come to light, often by chance, and some of these can be exploited industrially. At the same time new principles are established which give rational direction and lead to crucial improvements in industrial processes that had hitherto been purely empirical. It is naturally physics and chemistry that have had the most extensive use in the field of technology, because industrial processes deal mainly with dead material. But biology has made important contributions to the two great practical arts of medicine and agriculture, and we are now on the verge of far-reaching social developments in which the applications of biological and psychological knowledge will play a commanding part.

We must not underrate the scientific importance of the enormous amount of work that is now done in technological laboratories attached to industrial firms, instituted or assisted by Government, and sometimes attached to universities. Not only is it necessary to improve and perfect established industrial processes and to learn how to exploit new scientific discoveries on an industrial scale, but also in the course of such work new scientific problems emerge which have to be solved if further advances are to be made. Some of these problems can be tackled in the technological laboratory itself, others are remitted to laboratories of pure science. Some technical laboratories, indeed, though founded solely for work in applied science, do in fact spend part of their time in pure scientific research on problems chosen from the particular field. Thus pure science and technology act and interact to the advantage of both, and so it must always be. While insisting on the essential distinction between them, we must not forget that the two are in one sense parts of a whole—a whole which has a fundamental unity given by the consistent application of the scientific method to every sort of problem, whatever the material and whatever the object. But the immediate object, which carries with it the specific motive, does determine the nature and scope of the results.

We have defined pure scientific investigation as the pursuit for its own sake of coherent knowledge of the phenomenal world, and the essence of its being is psychological. The motive actually at work here is nothing else than scientific curiosity, the satisfaction of which is the discovery of new objective truth—of new facts which can be fitted into the framework of pre-existing theory, which require its modifications or restatement, or which demand new theoretical formulations. Technological research has other primary motives. It is always concerned with the solution of a problem for practical purposes. Behind it may lie the motive of making increased profits, or the motives of saving labour, of curing or preventing disease, or of promoting the health and well-being of the population. Several different motives of this kind may be involved at one and the same time, but they are all concerned with direct practical ends.

We must recognize that human motives are often, if not generally, mixed. A man may want to benefit humanity and at the same time to increase his income, and the two very different impulses may be served by the same action. He may also at the same time be moved by genuine curiosity about the solution of his practical problem and experience the joy of discovery when he is successful. The professional scientist, entirely devoted to his research with the unique object of discovering new fragments of truth, cannot ignore the necessity of earning his living. If he were no longer paid he would have to find other employment. But these facts do not affect the truth that the structure of pure science has been built up by men who sought knowledge for its own sake without regard to practical ends, and the further truth that without their work modern technology would never have been possible. If the disinterested pursuit of knowledge were to cease, the structure of science would cease to grow and the springs of all fundamental advance in technology would be dried up. That is one reason why we must uphold the claim of free research in pure science to an assured place in our society.

But it is by no means the only one. Science is indispensable to our complicated material civilization: it has also intellectual, ethical, æsthetic, and ultimately spiritual values of a high order. In the first place, its constant touch with the world of external Nature in which laws are at work that are uninfluenced by the vain imaginings of human beings keeps our feet on the ground, and should help to check the constant human tendency to fly off into ideological fantasies and to imagine that subjectively constructed and emotionally biased ideal schemes can without more ado be successfully applied to the real world—a tendency responsible for a large number of disastrous political mistakes. I am far from contending that objective sanity is the monopoly of men of science. On the contrary, there is unfortunately abundant evidence that employment in scientific work and even distinction in research is no assured safeguard against domination by misleading idealisms. But there can be no doubt that the scientific habit of mind, with its insistence on preliminary careful and accurate survey of facts and its constant testing of theory by fresh observations and experiments, is the master key to the devising of successful techniques not only in the material but also in the social and political spheres.

One of the best hopes for the future welfare of humanity is the beginning of unbiased investigation of social facts, of social psychology as well as what may be called social anatomy and physiology, and the influence upon these of economic and other environmental factors. The great man after whom these lectures are named clearly saw, sixty years ago, that we needed a real science of society which he proposed to call 'sociology', but it is only recently that the study has begun to assume a genuinely scientific character. Its development is seriously hampered because its field is also an arena of the strongest human prejudices and passions, as the older sciences are not. For many of us an impartial consideration of the facts revealed is very difficult indeed, because our feelings and our private interests are too deeply involved. Ideological constructions, of which the Fascist and the Communist theories of the State are current examples, gain numerous adherents because they satisfy certain human ideals and seem to provide remedies for current evils. In some countries they have been imposed by force, since they also serve the interests of ambitious individuals. Behind a façade of pseudo-philosophy or pseudo-science are concealed gross inconsistencies and often gross cruelties. Yet we must recognize that aspects of sociological truth inhere in the most extreme social and political theories, or they would not appeal, as they do appeal, to so many people of goodwill. For it must never be forgotten that every social theory that appeals to people of goodwill contains at least some element which corresponds with a deep-seated social need, however far it is from being acceptable at its face value.

It is the business of the new scientific sociologist to evaluate these elements in the light of social and individual psychology, as well as to accumulate, marshal, and determine the significance of the widest range of sociological, economic and political facts. It is the ultimate business of our statesmen to implement their mature conclusions. Statecraft, like agriculture and medicine, is a very ancient art, and on one side it must always remain an art. Human beings cannot be managed entirely by text-book rules, however good the text-books. But just as agriculture and medicine have become and are still becoming, to their immense benefit, increasingly scientific, by the discovery of the laws underlying the processes involved in the growth of crops and in the human body in health and disease, so the organization and management of human populations, which is the concern of statecraft in its widest sense, can be made increasingly scientific by the proper use of sociological and economic data. The making and still more the application of sociological generalizations demand bold constructive imagination but at the same time the greatest caution and the coolest judgment, precisely because they are so easily influenced and distorted by our prejudices and passions. A certain amount of 'flair', of empirical procedure, and of trial and error experiment are necessary, just as they still are in agriculture and medicine.

We may well ask whether our statesmen are sufficiently equipped for their part of this task, whether their prevailing mentality is of the kind which can freely accept the scientific method and apply it to their problems, whether they are not too hopelessly biased by so-called vested interests, of class, party, or money. This is indeed a very serious question. Ministers and high officials are constantly betraying their indifference to, or their distrust of, the scientific approach to practical problems, even in such matters as agriculture and food values, in which it is clear that only responsible scientists who have made the relevant investigations have any right to an opinion. It is often only under the stress of war conditions that far-reaching changes are made which have long been urgently required and strongly advocated by all informed opinion.

I am not suggesting that these things can be made right by putting scientists into ministerial offices. The professional scientist is no better fitted than any other professional man to deal successfully with affairs, to excel in administration, or to manage human beings. Indeed if he has become eminent in some particular specialized branch of science it is likely that absorption in his subject will have rather secluded him from those contacts with the world which are desirable if not necessary for a successful administrator. Nor would it meet the case to require every prospective minister and public official of high rank to take a course in elementary science! It is not specialized scientific knowledge that is wanted here, but the scientific spirit, an intelligent appreciation of what science really is and what it can do. We may acknowledge that the habit of consulting experts has increased of late years. But in the modern State with its innumerable problems demanding scientific knowledge and investigation, the scientific approach should be a matter of course, and the existing temper of Government and official circles is generally averse from such an approach.

A glaring example is the treatment of agriculture in Great Britain by successive Governments since the War of 1914–18. The basic cure for the ills of British agriculture has been and is the scientific approach to its problems combined with a statesmanlike comprehension of the part the land should play in the national economy not only in producing food, but also in keeping a substantial and contented fraction of the population in contact with the fruitful earth. It is of no use to keep juggling with prices and quotas, or to keep changing the Minister. What is wanted is a man of wide outlook and scientific imagination, who has a general knowledge of the advances that have been made in agricultural research, a readiness to take into his intimate counsels the men who really understand them in detail, and the courage and drive to push through the necessary comprehensive plans. Some part of the appropriate measures have been taken in response to the urgent needs of war-time for an increased native food supply, but they cover only part of the field, and we should like to be sure that they will not be discontinued as soon as peace is proclaimed.

What is needed is a complete change of heart, and it does not seem that this can be brought about except by a change in education. The current education of the men who are entrusted with the forming of Government policies has almost wholly ignored and frequently despised science. Though giving a grudging recognition to its contribution to their material amenities, many of these men regard science with a mixture of dislike and fear—dislike because it seems to them hostile to the traditional cultural values they accept, fear because they are apprehensive that its tendency is to destroy those values. I am not one of those who depreciate classical or historical education. I should look with alarm at the prospect of severance of our culture from its historical roots—the philosophy, literature and art of Greece and Rome—or from the historical channels through which it has developed. But there is no reason whatever why a liberal education in the old sense should not be extended to include a sound introduction to scientific culture. Time could be found by reshaping the curricula and omitting the unessential. I contend that education cannot justly be called liberal to-day unless it includes an introduction to science and the history of science, simply because science is a vital part of the culture fitted to the contemporary world.

The reformed liberal education that I have in mind must begin in the secondary if not in the elementary school. It should be the normal school curriculum and in the hands of teachers thoroughly imbued with its spirit and significance. It has nothing to do with so-called 'specialization' in science, which at present begins at too early an age and may easily have a narrowing effect on the mind, as can unfortunately be seen in many scientists and technologists who have specialized too early and who tend to despise the other disciplines. Narrowness of cultural outlook is not, however, confined to scientific men. I have heard in this University of Oxford historians and others who are supposed to have had a liberal education express almost incredibly narrow and short-sighted views about the place of science in education.

We have just been considering the essential importance of science and the scientific spirit in the economy and service of the State. But the re-orientation of education I have advocated would do far more than produce a new and better type of minister and high official. It would broaden and vivify the minds of all who experienced it, at least of those at all able to benefit by a liberal education. Equally with literature and art, science has its own contribution to make to the development of the mind, its own distinctive quality engendered by the habit of dispassionate objective investigation and of respect for objective truth. The scientific mentality forbids the unconditional acceptance of views and formulæ represented as authoritative but often motived by traditional bias or by selfish interest. It teaches humility and submission to the logic of established facts, and counteracts the arrogance of human prejudice and wilfulness. This is an ethical as well as an intellectual contribution. I do not contend, of course, that this particular moral quality is confined to men of science; only that it is an essential part of the spirit of science and that the wider diffusion of that spirit will powerfully aid the growth of the virtue.

Finally there is the æsthetic aspect of science, which opens the mind to a far deeper and wider realization of the wonder and beauty of the universe. This is not a trivial claim though it may seem to some old-fashioned. A real and deep æsthetic satisfaction is brought by the constant contemplation of the infinite beauty of Nature, ranging from the galaxies of astronomical space through the marvellous diversity of scenery and of the living beings inhabiting the earth's surface, to the fascinating world revealed by the microscope and the still more minute phenomena dealt with by structural chemistry and intra-atomic physics. The gradual discovery of these things and of the laws which explain their relations, constantly reformulated and made to fit the observed phenomena ever more closely, is indeed a marvellous and majestic story, a story in which the human spirit can find refreshment and escape from the conflicts and tragedies of human life just as it can find escape and refreshment in the finest literature and the greatest music. The very impersonality of the subject-matter of science makes the refuge particularly complete. I recall that the group of men who afterwards founded the Royal Society sought refuge in the peaceful atmosphere of their experiments and discussions from the increasing political tension of London during the conflict between king and parliament. If the fashionable and facile charge of advocating 'escapism' is brought against me, I can only reply that the possibility of 'escape' in this sense is absolutely necessary to mental health and stability in the modern world.

Scientific culture, then, must take its place on equal terms beside the literary and artistic cultures. Entirely apart from its indispensability for the material comfort and the safety and health of modern urban populations, science has intellectual, ethical and æsthetic claims of a very high order. Its achievements are particularly characteristic of our own age. During the last half-century Europe has not produced poets or musicians who can compare with Shakespeare or Goethe, with Beethoven or Mozart, but it has produced several men whose discoveries are equal to the greatest in the history of science and very many of conspicuous talent, though not of genius, who have contributed between them a much larger body of sound scientific work than has been produced in any comparable period of history. Why then, we naturally ask, is science regarded with dislike and distrust by too many cultivated people who are supposed to have had a liberal education, and by the great majority of the population as a rather mysterious, esoteric agency which produces all sorts of marvellous mechanical contrivances but in which they have no part or lot? It is, I think, because scientific education has been kept in watertight compartments and almost exclusive stress has been laid on its material achievements to the neglect of its cultural values.

It may be objected that it would be impossible to give the masses of the population a liberal education in science, that science for the vast majority can never mean more than technical training in some particular branch that is materially useful. But if the hopes of progressive educationists are realized the aim of the future must be to put a liberal education within reach of everyone. It is my contention that a liberal education in any full and worthy sense must include a broad introduction to science, along with the other elements of knowledge and training which develop the mind, widen and deepen its scope, and do all that education can do to produce citizens equal to the opportunities and responsibilities of the future. It is perfectly true that only a minority of pupils will ever profit at all fully from such an education. A process of sifting must take place in the elementary school and in the secondary school, and only a small proportion of pupils will reach the university. Such a process exists now, though it is very imperfect: in the future we must give the fullest opportunities to all, irrespective of means or social class; but selection corresponding with ability and natural endowment there must always be. It is also clear that specialized training for the work of adult life is necessary, that it must be widely different according to the opening for different kinds of such work, and that it should be adapted to the natural bent and capacity of the individual. A great many pupils have no inclination or ability for scientific work, just as various others have no capacity for music, or for mathematics, or for languages, or for administration, or for craftsmanship. All this, of course, is the merest educational commonplace.

What I am advocating is that all should receive the elements of a liberal education, including a broad and real introduction to science in the secondary school, that for pupils of the greatest general ability specialization should be deferred to a later age than it is at present, so that general education could be carried further and a better and wider culture opened to the best growing minds. In this way a juster balance would be reached between the different aspects of human knowledge and a more secure foundation would be laid for a proper choice of occupation. Science would be placed in its proper light before the eyes of growing youth as one of the great channels through which man's creative powers can find expression, without the almost exclusive emphasis on its technological functions which is now prevalent. Most of those who chose a scientific career at any stage of their education would no doubt enter one of the great fields of the application of science to human use, both because the volume of employment in the technological field is and will continue to be much more ample, and because the qualities required in many such posts are much commoner than those necessary for the successful pursuit of pure research.

A comparatively small minority would engage in research or in teaching combined with research, as they do now, but this minority would be powerfully reinforced, in quality as well as in quantity, by drawing on hitherto untapped resources of the population. Comparatively rare as the combination of marked ability and strong inclination for research in pure science may be, there can be no doubt that it exists in many who at present have no opportunity of following their proper bent. The liberal school education I am contemplating should help to free the minds of those who follow any kind of scientific career from the distressing and harmful narrowness some of them now display. At the same time the acquirement of some knowledge of the real nature and significance of science should also help to abolish the equally distressing and harmful dislike and distrust of science among others to whom I have alluded.

Science is part, and by no means the least important part, of our cultural heritage, though it cannot, of course, satisfy the whole range of man's spiritual demands. We are often told that science alone is not enough, that its essentially mechanistic analysis of phenomena, not only the phenomena of the external world but of the mind itself as they are revealed by modern psychology, does not touch the essence of the human soul and cannot explain the highes values of which we are conscious. That I freely admit Certainly we cannot do without literature, art and music, nor can we dispense with religion in its wides sense. What I assert is that science, too, makes it own contribution to spiritual values, and that to limit its function to the material sphere is to impoverish our culture most disastrously.

The recent movement which exalts the materia function of science and denies the right of pure science to an independent existence is a kind of philistinism which plays into the hands of those who dislike and distrust science and are only willing to concede it material services. One of the leaders of this movement tries to bolster up his case by rather childish misrepresentations of the motives of scientific research, suggesting that scientific curiosity i "not particularly noble", that the joy of new discovery, the delight in establishing some new fragment of objective truth, of contributing, in howeve small a degree, to a clearer insight into the orde of Nature, are not the dominant impulses and feelings of the worker in pure science, that he i more often actuated by a desire to rise in the world and that he will gladly turn his back on research to become an administrator. Such contention are flatly contradicted by the experience of thos actually engaged in research, who have the bes opportunity of observing the dispositions and behaviour of their fellow-workers. That many scientist do in fact turn to administrative work in their late years is perfectly true. The ardent curiosity of th true investigator and his capacity to continue th strenuous though delightful mental work involved in continuous research often weaken as the mind loses its early vigour, though some minds retain them throughout mature life. Nor can we assert that th attractions of an easier life and a larger income ar negligible, especially to those who are conscious o the weakening of their earlier impulses. But th existence and effectiveness of these other motives in such cases do not affect the truth that the actua motives of pure research are highly characteristi and remarkably strong and pure. The evidence i plain to all who will look at the facts, unless they wish to believe the contrary.

The main contention of this school of thought is as we have seen, that research in science is alway governed, consciously or unconsciously, by curren social needs, and that we should now deliberately organize or 'plan' all research with the immediat object of continuing to satisfy those needs. Tha 'planning' must play a very large part in our futur social and economic life I should be the last to deny It is equally true that most technological work mus be planned and that even in the realm of pure scienc there are problems that can only be dealt with effectively by directed teams of workers. This applie particularly though not exclusively to much exploratory work and to preliminary surveys of wide scope But the highest type of research, that which has been productive of the most fundamental discoveries, i essentially the work of individual minds, freely dealing with their own chosen material. That is the evidenc of the whole history of science. If we desire to keep alive and vigorous the ultimate springs of ou material welfare, and—not less important—to maintain and extend the place of science in our culture we must jealously guard its freedom and its independence.

PORTABLE MASS SPECTROMETER

By JOHN A. HIPPLE, jun.
Westinghouse Electric and Manufacturing Co.,
East Pittsburgh

THE mass spectrometer illustrated below was developed at the Westinghouse Research Laboratory in East Pittsburgh as a tool for some routine gas analysis problems. A rather complicated mass spectrometer had been used for this work; experience with this apparatus indicated that it would be desirable to have a compact, self-contained unit that could be moved to the position where a gas analysis was desired. The result of this was the development of the present instrument.

In contrast to the Aston type of high-precision instrument, high resolution is not so important here as high sensitivity and ease of measuring quantitatively the amount of ion current. For this reason the current is measured electrically. This mass spectrometer uses the focusing properties of a magnetic field described by Barber[1] and Stephens and Hughes[2,3]. Instruments using this principle have usually used a magnetic deflexion of 60°. Examples of this are the instruments of Bainbridge and Jordan[4] and Nier[5]. As is evident from Fig. 1, a deflexion of 90° has been used in the instrument here described. In the figure, the magnet has been withdrawn from its operating position to permit a better view of the tube itself. The 90° deflexion has been used for compactness, decrease in the ion path-length and simplicity of alignment and operation. The vacuum envelope is made entirely of glass and the electrodes are made of 'nichrome'. The tube is made in a jig and, when it is removed from the jig, no further alignment is necessary. The ions are shielded from the glass in the analyser region by means of a flexible 'nichrome' shield which fits inside the glass tube. The slits are of the order of 0·020 in. and the radius of curvature of the ions in the magnetic field is 5·0 in. With this geometry, the resolving power is about one mass unit in one hundred.

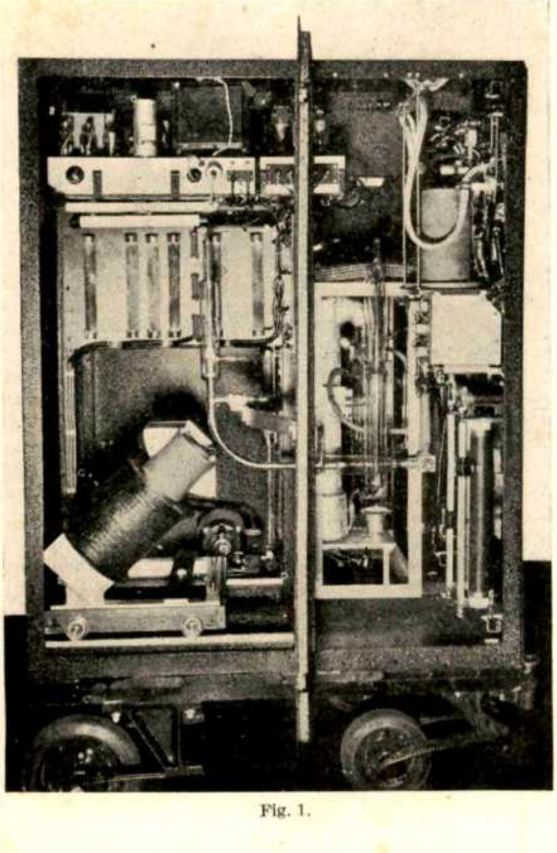

Fig. 1.

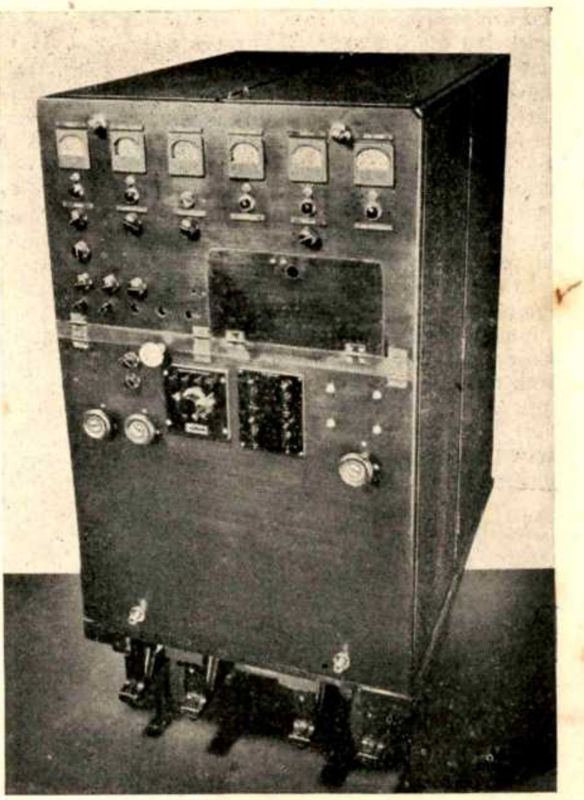

Fig. 2.

The magnet coils are wound with many turns of fine wire so that the maximum field is obtained with a voltage of 800 volts and a current of 0·100 amp. The power supply is an electronically stabilized rectifier shown at the top of Fig. 1. This 1,000-volt power supply also provides the accelerating voltage for the ions. Since the ion-accelerating voltage and the magnet voltage are provided by the same supply, an additional regulation is obtained as well as an economy in design.

The pumping system consists of two glass mercury diffusion pumps backed by a mechanical forepump. The diffusion pumps and the gas handling system for admitting the gas to the mass spectrometer are mounted on a sub-assembly which can be removed from the main assembly in a few minutes.

The ion current is measured in a conventional way by means of a sensitive electronic current meter. This instrument is mounted in an evacuated housing with sensitivity adjustment by a control on the front panel. The power for this instrument is provided by an A.C.-operated direct-current supply which is electronically stabilized. Another stabilized source provides the voltage for the electrons in the ionization chamber.

The entire apparatus is enclosed by a frame with steel panels except the front which is 'Micarta'. All sides and the top of the enclosure are provided with either hinged doors or panels which snap into position and are easily removable. In this way, there is ready access to all parts of the instrument. Fig. 1 is a view showing the side open, while Fig. 2 illustrates the complete unit ready for operation. It will be noted that the entire assembly is mounted on a truck for easy movement to any part of the building. Since the mass spectrometer is operated completely by alternating current, the only connexions to be made when the unit is in place is one to the A.C. voltage supply and water connexions for cooling the diffusion pumps.

In addition to the features of compactness, ease of operation and portability, the design permits ready shipment from one place to another, since all the component units may be removed in a short time from the main assembly. As an illustration, the first apparatus of this design was sent from Pittsburgh to New York (400 miles), operated in New York for a week and then returned to Pittsburgh without mishap and with very little trouble.

CARE OF WORKS OF ART IN WAR-TIME

By F. IAN G. RAWLINS

BY 'care' in normal times is probably understood due conservation and maintenance; this in fact is the elemental work which devolves upon curators of any collection of works of art. In times like the present, however, two novel aspects appear: one is protection against enemy action, and the other—a kind of dependent variable—is the greatly increased difficulty of ensuring proper care (in the usual sense) which the necessity for such protection tends to bring about. In other words, there is a distinct possibility of devising excellent 'cover' but at the same time exposing the treasures to such risks of damage and deterioration by inadequate transport and storage arrangements, that the verdict of posterity may well be, "If only they had been left where they were. . . ."

This is not merely to seek a nice balance in policy: sooner or later—perhaps sooner—a decision will have become vital; and if, as this article assumes, the plan amounts in effect to evacuation, then it is not a matter to be taken lightly. The hazards may indeed be severe. However, it is by no means my intention to make too much of them. Many can be overcome, and have in fact been overcome. But they are always there, and for the most part, experience to cope with them is not very extensive.

Clearly, evacuation is unjustifiable unless it is reasonably certain that the sum total of the chances of destruction (not only those due to hostilities) is thereby definitely reduced. There are, broadly, two alternatives: (1) dispersal, (2) deep shelters, for example, quarries, tunnels and so forth. The former amounts in practice to the use of country houses as repositories, sending a comparatively small number of objects to each; the latter is more drastic and will probably end in putting the whole collection underground in one place. Which of these methods is chosen will naturally depend upon considerations outside the scope of this contribution. The intention now is to discuss ways and means of securing a tolerable exile.

Dispersal

Technically, private houses, public halls and buildings of that category present a number of complexities, which make it most important to examine them in detail beforehand. For example, the flooding of basements (otherwise promising storages) is sometimes to be apprehended. The fire risk is usually considerable; appliances will almost certainly need augmenting. Moreover, for books and pictures especially, if the only way of dealing with an outbreak is by water, the curator may even be well advised to avoid the scheme altogether, since the damage suffered would probably be almost irreparable. Generally, the only effective safeguard is to have staff always available for instant salvage in case of fire. This implies the availability of a spare 'sanctuary'. The possible presence of dry-rot in timber floors should not be overlooked. In many instances woodwork can be adequately protected in occupied premises against mould growth and from becoming infested by bacteria by the application of a 10 per cent solution of copper naphthenate in paraffin. Fireproof paint or solution should be applied where desirable, both to wood and to any hangings or curtains used to exclude draughts or to form parts of air-locks. The majority of precious objects are most unlikely to be injured by war gases in vapour form. Splashes of the liquid, however, are almost sure to be fatal on books, manuscripts, pictures and textiles. 'Cellophane', oilskins, rubber fabrics, decreasing in effectiveness in that order, form reasonably sound protective coverings.

The most important factors of all are likely to be temperature and relative humidity (R.H.). It is usually considered that most museum materials and exhibits are well provided for at a temperature of 60° F. and 60 per cent relative R.H. Research on this subject is as yet insufficient to enable exact figures to be stated, but there is some reason to suspect that the traditional values of 60° F. and 60 per cent R.H. have been accepted more on account of the comfort of visitors to galleries than on behalf of the contents. While temperature *per se* is not of the greatest moment, relative humidity assuredly is. It seems likely that a range of between 50 and 55 per cent at around 60° F. is nearly ideal. Fluctuations in relative humidity such as commonly occur in most buildings at certain seasons of the year are most undesirable. They may produce strains leading to complete breakdown in some pictures (panels in particular), and to a lesser extent with other objects.

The control of relative humidity in war-time storages is exceedingly difficult; so much so indeed as to constitute a major problem. Obviously, fairly simple measures, capable of being implemented more or less on the spot, are all that can be reasonably expected. The main question is how to combine adequate ventilation with satisfactory constancy of relative humidity without elaborate machinery. It is easy enough to install some electric (preferably tubular) heating in a store room, and even to maintain an approximately level temperature, piercing doors or partitions to gain free air-circulation. But it will usually be found that the relative humidity varies over very wide limits, simply repeating the day and night changes that occur outside. The range may well be between 40 and 70 per cent or more. These are definitely dangerous limits.

In my experience there is only one course to adopt, and that to some degree at variance with customary methods. It is to seal off the storage chamber as effectively as possible from external influences, by stopping up doors, windows and cracks, and by hanging up heavy felt or similar material. Then small electric fans can be used, suitably orientated, to stir up the air inside the storage chamber itself. Fresh air can, of course, be admitted, when weather conditions are favourable, for a short time. Given reasonable heating, the relative humidity should be roughly constant. That is one point gained. If it settles down to a figure unduly high, say above 65 per cent (see later for the significance of this) more well-dried fabric may be introduced, or the temperature raised, so long as it does not in general exceed 70° F. If the relative humidity is too low, the temperature may be lowered a little, and wetted material suspended. It is probably prudent to avoid chemical drying agents like calcium chloride or phosphorus pentoxide in the same room as valuable objects. It will doubtless be noticed that the more hygroscopic material there is in the chamber the less sensitive does it become to abrupt changes of relative humidity.

Wherein this treatment differs from that commonly envisaged is its insistence upon constancy of relative humidity even at the expense of 'proper' ventilation. Naturally, if reasonable freedom from fluctuations in relative humidity can be obtained with air-flow from outside, so much the better; it appears, however, to be a most unlikely state of affairs to find (or even to attain) in war-time quarters.

Instrumentation may well be on a simple scale. Thermostats can be efficient for temperature control, but some method of testing the relative humidity regularly is essential. A psychrometer, or whirling hygrometer, is the obvious way, though recording instruments are useful adjuncts if periodically checked. At least they show the general trend.

Deep Shelters

These are inevitably in the nature of a long-term policy, and probably out of the question for the majority of institutions and private owners. Nevertheless, they are of great importance, and of considerable scientific interest. Clearly, no perishable material of value can be stored in quarries, caves, tunnels and such-like places without elaborate preparations on the site. The chief enemy is damp; the fire-risk, on the other hand, should be diminished compared with that for isolated houses. Other hazards, less obvious perhaps but sometimes no less severe on that account, are flooding, noxious vapours and gases, dust and falls of roof. These points are excluded from further discussion, since any proposed underground repository where such dangers exist would naturally be rejected out of hand.

We are left, therefore, with the ever-present problem of temperature and humidity control. One favourable factor may be expected to appear immediately, namely, that in many subterranean workings the temperature is approximately constant throughout the year; but the relative humidity may be high—around 90 per cent—and fairly even. Thus, it will be necessary either to erect buildings inside, or to block off suitable portions of the space and to 'condition' them as effectively as may be needed. Which method is adopted will depend largely upon the type of rock strata involved, and to some extent upon the shape and general lay-out of the place. The class of material to be stored will also weigh. If the natural temperature is low enough (around 45° F.), it may be possible to obtain the relative humidity required, say, 55 per cent at 60° F., by straightforward temperature control alone, without recourse to refrigeration, except perhaps temporarily, to hasten the process of drying out. If this is so, and electric power is available, as it supposedly would be in many cases—the project becomes quite tractable. In fact, conditions approaching the ideal can be realized relatively simply, given sound initial equipment and constant supervision. A stand-by generating plant in case of power failure is, of course, essential.

Repositories of this kind represent a type of scheme 'easier said than done', however; difficulties of a somewhat crude nature are apt to appear very early in the proceedings. One is often that of access, both to the site itself and to portions of it below ground which theoretically are the most advantageous to occupy. It should always be borne in mind that priceless and irreplaceable things are to be brought there (since such a plan would never be contemplated for minor exhibits), unloaded and perhaps unpacked, put in place and duly invigilated. In addition to which it may be necessary to allow for objects of great bulk combined with excessive fragility—altogether not an enterprise to be embarked upon too lightheartedly. A good feature awaiting us, however, is that quarry—and some other—adits are often far from straight, which is a great advantage in forming natural baffles against the propagation of blast.

General

There remain a few general considerations common to any programme of evacuation and war-time storage of valuables and perishable objects. One is that of avoiding the growth of mould or mildew. A relative humidity so low as 68 per cent has been found to permit of mould growth, especially at temperatures around 70° F., showing that raising the temperature is not in itself any security, if the relative humidity remains excessive. Good ventilation, or at least adequate air-movement, is a safeguard. Another matter concerns lighting. Some illumination is desirable as a check upon mould growth itself. In addition, for pictures less than about fifty years old, there is a tendency for the medium to turn yellow, especially if of a 'fat' nature. This process is favoured by darkness. For older paintings, oxidation is probably complete, and no colour change need be expected as the result of storage away from light, so far as the medium is concerned. Water colours and miniatures should always be stored away from light. Where possible, objects should be unpacked to facilitate inspection, and to give the best chance of air circulation.

Generally, there can scarcely be hard and fast rules, except perhaps to recollect that flooding, exposure to excessive relative humidity, attacks of mildew and—no less—inadequate or rough transport may bring about damage amounting almost to disaster. None of these things should stand in the way of seeking the safest place for works of art. But 'watch and ward' was never more urgent.

Some scattered literature on the subject began to accumulate as the result of the Spanish Civil War.

Since then two valuable contributions have appeared: (1) "Air-Raid Precautions in Museums, Picture Galleries and Libraries" (British Museum Trustees, 1939) and (2) "Preservation of Paintings in War-Time" by G. L. Stout (Fogg Art Museum, Harvard University, U.S.A., 1942). Meanwhile, data are being assembled from day to day as the result of experience in war-time repositories. Much of it would never have been obtained in years of peace. Some of it will doubtless be significant for future planning of museums and galleries.

OBITUARIES

Sir Daniel Hall, K.C.B., F.R.S.

SIR DANIEL HALL—long known simply as A. D. Hall—had an unusually wide circle of friends who will deeply mourn his death on July 5 at a nursing home in London.

He was born at Rochdale on June 22, 1864, and was educated at the Manchester Grammar School, where he already showed wide scientific interests and was equally keen on chemistry, physics and the field sciences, botany and geology. From Manchester he gained the Brackenbury Science Scholarship to Oxford and entered Balliol College in 1881. Here he was soon recognized as possessing entirely exceptional qualities and he lived a very full life. At no time was he a narrow specialist, least of all during these formative years at Oxford. Everything he touched he did well, whether it were science, athletics, or participation in the various movements then forming part of Oxford life. He rowed in the Balliol eight and he laid the foundations for those wide intellectual and artistic tastes which characterized him throughout his life and added so much to his personal charm. At Oxford, too, he was fortunate in his choice of friends, many of whom afterwards had distinguished careers. He did not remain at Oxford, but left in 1884 to become a science master at King Edward VI Grammar School, Birmingham, where he met his first wife, Mary Brookes, and wrote his first book, a little text-book for the use of his students. He soon gave up school teaching and for a time served as lecturer in the university extension movement then beginning; Kent and Surrey were his counties; they were then more rural than now. Here he became interested in agricultural education and he soon saw that if it was to be effective it must be systematic and continuous; occasional lectures were quite inadequate. He was able to persuade a very public-spirited gentleman, E. J. Halsey, of the soundness of his views, and Mr. Halsey saw that funds were provided for establishing an agricultural college. Hall knew the two counties well, and selected the old Latin school at Wye as the proper place; it was a medieval foundation with attractive old buildings that gave the setting he always liked so much. He took possession in 1894 and was able to add laboratories and new buildings without doing violence to the old ones.

Hall was ably supported by a group of able men: F. B. Smith, J. Percival, F. Theobald, T. R. Robinson and H. H. Cousins, and between them they worked out systematic courses on agricultural science and practice, and trained numbers of young men who afterwards held very important posts at home and abroad. Hall insisted that the teaching must not only be based on sound science but must also constitute a new science, always drawing on practical agriculture for its materials and its illustrations. He set the example by becoming a first-class grower of fruit, hops and flowers, especially roses, tulips and sweet peas; he could hold his own with any expert, and the farmers and gardeners of Kent quickly recognized him as a fellow-craftsman of outstanding distinction. He was equally successful in dealing with farmers; he was a remarkably shrewd observer and could quickly detect the flaw in management which had led to some unsatisfactory condition of crops or animals. The early prejudice against agricultural education could not stand up against ability of this sort, and before long the high position of Wye was assured.

Hall always recognized, however, that both the teaching and the advisory work then beginning to develop were limited by the amount and value of the science on which they were based, and very soon this began to be insufficient. There was at that time no provision for research; education was supposed by the administration to be a proper object for State aid, but not research, which was regarded as something entirely distinct and unrelated. Hall set himself to remedy this defect; he gave up Wye at the height of its success and in 1902 went to Rothamsted in succession to Gilbert; he found the whole place moribund, but with characteristic energy and devotion proceeded to put new life into it. He had neither staff, apparatus nor funds and was snubbed by the Board of Agriculture when he asked for a grant, yet his infectious enthusiasm attracted first men then money, until finally he had built up a compact team of research workers who opened lines of investigation that have since proved very fruitful. The Goldsmiths Company gave a handsome endowment for soil research and this lead has been followed by a long line of generous supporters.

Once again, however, Hall felt impelled to give up the work when he had got it well on the road to success. In 1909 Mr. Lloyd George set up the Development Fund for the purpose of developing agriculture and improving rural life, and he appointed a small Commission, including Hall, to administer it. Hall soon became the dominating figure and in October 1912 was induced to give up Rothamsted so as to devote his whole time and energy to the work. The full story has not yet been written, and reference can be made here only to that part dealing with research and education. It was agreed that agricultural research was to be greatly developed. Two methods were possible: the establishment of a large central research station covering all branches of agriculture on the model of the United States Department of Agriculture at Washington; or a number of smaller stations attached to the universities, where different branches of agriculture or agricultural science would be studied. The latter method was chosen, and there is no question that the decision was sound. Agricultural science has developed remarkably well in Great Britain as the result of the freedom conferred by the new arrangements, which were indeed the envy of scientific workers from other countries when they came over here. A very effective advisory service was also set up and the educational machine was greatly improved. Later experience has shown that these three services could well have been more closely linked, but there is no evidence that Hall was responsible for that defect. He certainly achieved a great amount of most useful constructive work.

Then in the War of 1914–18 came another change; at the crisis in 1917, when 'total war' was forced upon us and all peaceful activities had to be abandoned, Hall gave up the Development Commission and became Permanent Secretary to the Board of Agriculture under his old friend Prothero (afterwards Lord Ernle) as Minister. Here he was less happy than in his previous posts; he gave the impression that he found office routine very irksome; all his life he had been accustomed to prompt decision and speedy action, and in any event the times were unpropitious. When Bateson died in 1926 Hall accepted the directorship of the John Innes Horticultural Institution at Merton, retaining only a part-time connexion with the Ministry of Agriculture as its scientific adviser. Once more he was back in the atmosphere he loved; his coming, Darlington said, was like a breath of fresh air; and he rounded off a life-time of experience and observation of tulips and apples by producing two monographs which are not likely to be superseded in our time. He stayed on until 1939 and then retired, but only to change his occupation. He had always been interested in the Lord Wandsworth Agricultural School at Wantage, and as chairman of the governors he went to live there so that he might keep closer touch with its activities.

Few men can have lived a fuller life or one more helpful to the community. His influence will last long after our time, and the beneficial activities he started will go on bearing fruit, while his memory will be an abiding inspiration to all who had worked with him. E. J. RUSSELL.

Prof. D. la Cour

PROF. DAN LA COUR, director of the Meteorological Institute of Denmark, died at Copenhagen on May 19 at the age of sixty-five; his death will be deeply regretted by geophysicists throughout the world. During the past fifteen years or more he took an increasing part in international leadership in geophysics, the science for which above all others international co-operation is essential; at the time of his death he was president of the International Union for Geodesy and Geophysics. He was elected to this office at Edinburgh in 1936, and would normally have vacated it in 1939, but at the Washington conference of the Union, held just after the outbreak of the present War, new elections of officers were postponed; his advice and guidance in re-starting the work of the Union when peace returns will be greatly missed.

Prof. la Cour was born at Copenhagen on September 12, 1876, of a family of high distinction in Denmark; his father was a High School physics master. After completing his university studies at Copenhagen, he became an assistant of the Meteorological Institute in 1900, under the directorship of van Ryd; in the year previous to this he took part in a Danish auroral expedition, and during 1900 he was leader of this expedition. From 1903 onwards he took charge of the Department of Weather Services, and from 1920 also of the Magnetic Department. In 1923 he became director of the Institute. From 1908 onwards he lectured on meteorology at the famous Copenhagen Polytechnic Institute. In 1927 he was elected to the Danish Academy of Sciences, and in 1939 to the Danish Academy of Technical Science. He received also many honours from other countries, and held numerous important offices in international scientific bodies.

Among the services la Cour rendered to the advancement of geophysical observation, one of the greatest was connected with the plans for the repetition, in 1932–33, of the International Polar Year of 1882–83, when the leading nations co-operated in sending expeditions to various parts of the north polar regions, in order to make meteorological, magnetic, auroral and other observations throughout a whole year. The project for a renewal and extension of this work, with modern instruments and methods, in the jubilee of the original polar year, was mooted in good time for new expeditions to be planned, and in 1928 the International Meteorological Committee appointed a commission to organize the work. In 1931, however, the world economic crisis deepened, and there was danger of the project being abandoned; la Cour was foremost in withstanding this, and under his leadership, as president of the International Polar Year Commission, the great enterprise was carried through to success.

In facilitating afterwards the use of the large mass of new data thus obtained, la Cour likewise played an important part, with the enlightened generous support of the Danish Government. An international bureau was set up in his Institute, and there he organized the reproduction, on micro-films, of the magnetic and some other data. In this and his other work he and the skilled staff he gathered around him achieved first-rate results with great economy of money and effort.

He extended the scope of Danish observations in geomagnetism by establishing (in 1927) a permanent magnetic observatory at Godhavn, in Greenland (only 10° from the pole of the earth's magnetic axis), in addition to the long-existing Copenhagen observatory (now at Rude Skov). He also started a new series of Danish geomagnetic publications ("Communications Magnétiques") to supplement the Danish magnetic observatory yearbooks.

La Cour also aided geomagnetic science very greatly by his many improvements in the design of magnetic instruments, through which the accuracy and reliability of magnetic observations and records were notably raised. He overcame several inveterate difficulties that long hindered the attainment of the high degree of precision aimed at in geomagnetic measurements. One such difficulty was connected with the use of fine quartz suspension fibres. The usual clamping of their ends did not prevent slipping, and injured the fibres: la Cour, who was himself an adept in their manipulation, left a quartz drop at each end of the fibre, and placed each drop in a simple mounting of special design; subsequent light heating fused the quartz and provided a safe connexion with the holder. Again, the magnetic balance, for the continuous measurement of the vertical magnetic force, is exceptionally sensitive to slight changes in the position of the magnet relative to the knife edges on which it is balanced; la Cour avoided any such displacements by making the magnet, knife-edge and mirror in one piece, of tungsten steel, weighing in all only 2·5 gm. He also introduced a simple, ingenious and satisfactory method of optical temperature compensation for magnetic recorders. His improvements probably have valuable applications in other branches of observational and experimental physics. Only a few of his instruments and devices are mentioned here; a paper describing the latest of his instruments, for the measurement of the vertical magnetic force, reached England only a few days ago.

La Cour did much by example, precept and international intercourse to promote the improvement and extension of magnetic observations, and the intercomparison of magnetic standards. I was privileged in 1936 to accompany him on a tour with this object, to magnetic observatories and institutes in Sweden, Finland and Russia; he was a most kind, courteous and agreeable companion.

He was a tremendous worker, and was remarkable also for his capacity to inspire others with the same ardour, to an extent that perhaps sometimes surprised even themselves. His manner and his dignified movements suggested calm, irresistible strength.

La Cour was married and had one son and four daughters, who with Mrs. la Cour survive him. On his international journeys he was often accompanied by one or more members of his family, and in consequence there are many countries in which a personal sympathy with his family will be felt in their and our loss.

S. Chapman.

We regret to announce the following deaths:

Prof. J. C. Arthur, emeritus professor of botany since 1915 at Purdue University, and president in 1902 and 1919 of the Botanical Society of America, known for his work on the plant rusts, on April 30, aged ninety-two.

Mr. F. C. Baker, curator emeritus of the Museum of Natural History of the University of Illinois, corresponding member of the Zoological Society of London, on May 7, at the age of seventy-four years.

Dr. G. B. Batten, a pioneer of X-ray treatment, who was president during 1918 of the Röntgen Society, on July 9, aged eighty-one.

Dr. Charles R. Keyes, consulting mining engineer, founder and editor of the *Pan-American Geologist*, on May 18, aged seventy-seven.

Dr. M. W. Lyon, jun., pathologist of the Clinic, South Bend, Indiana, and president during 1931–33 of the American Society of Mammologists, on May 19, aged sixty-seven.

NEWS and VIEWS

Charles Blacker Vignoles and the Royal Society

At a meeting of the Royal Society on July 16, a gold snuff-box, once the property of Charles Blacker Vignoles, F.R.S. (1793–1875), was presented to the Society by his grandsons, Mr. E. B. Vignoles and Lieut.-Colonel W. A. Vignoles. Mr. Vignoles, in making the presentation, referred to the fact that in 1841 C. B. Vignoles presented to the Royal Society a fine portrait of Sir Isaac Newton, which had come to him as the result of a connexion between his mother's family and that of Sir Isaac. Mr. Vignoles said that his grandfather, who was of Huguenot descent, came of a long line of soldiers and was an orphan and a prisoner in French hands at the age of thirteen months. He was educated by his maternal grandfather, Dr. Charles Hutton, F.R.S., the mathematician, the author of "Hutton's Logarithms", in the preparation of which Vignoles assisted. As a young man he served for a time in the Army, taking part in the disastrous attack on Bergen-op-Zoom in 1814. Following the peace after Waterloo, he went to America, where he was engaged on survey work in South Carolina and Florida, then very little known. Returning to England in 1823 he was soon engaged in railway engineering, almost his first work being the first survey for the proposed Liverpool and Manchester Railway. In the course of a long career he carried out important work at home and abroad as a railway and civil engineer, including the great suspension bridge over the Dnieper at Kieff and a railway through the Cantabrian Pyrenees from Bilbao to Tudela, which with its sharp curves and bold moving of a river, struck a new note in railway engineering. The 'Vignoles rail', the flat-bottomed rail of his design still used all over the world, keeps his name familiar to railway engineers. Vignoles was elected a fellow of the Royal Society in 1855 and was president of the Institution of Civil Engineers in 1870–71.

The snuff-box, now presented to the Royal Society, was given to Vignoles by the King of Württemburg, in 1844, as a mark of his esteem, after Vignoles had advised the King on plans for the railways of the State. The snuff-box is of solid gold with a portrait of the King set in diamonds on the lid; inside the lid is an inscription in French giving the circumstances of the presentation and signed by Goes, Secretary of State of Württemburg.

Social Medicine at Oxford

The Nuffield Provincial Hospitals Trust, with the approval of Lord Nuffield, is to devote £10,000 a year for ten years to the creation in the University of Oxford of a University professorship of social medicine, and the foundation of an institute in which the professor will work. The purposes of the institute are: "To investigate the influence of social, genetic, environmental, and domestic factors on the incidence of human disease and disability. To seek and promote measures, other than those usually employed in the practice of remedial medicine, for the protection of the individual and of the community against such forces as interfere with the full development and maintenance of man's mental and physical capacity. If required by the university to do so, to make provision in the institute for the instruction in Social Medicine of students and practitioners of medicine approved by the Board of the Faculty of Medicine in the University of Oxford."

Scientific Men in War-time

A deputation arranged by the Parliamentary and Scientific Committee saw Mr. R. A. Butler, president of the Board of Education and chairman of the War Cabinet Scientific Advisory Committee, who was accompanied by Prof. A. V. Hill, on July 16, to urge the Government to set up a full-time scientific and technical joint board. This would have as its aim the fullest strategic use of scientific man-power and resources and the proper organization and exchange of scientific and technical information relating to the war effort. The deputation included Lord Hinchingbrooke, Lord Leverhulme, Lord Pentland, Lord Samuel, Sir Lawrence Bragg, Capt. L. Plugge, Prof. B. W. Holman, Dr. W. Wooldridge, Mr. J. H. Wootton-Davies, and representatives of the British Association of Chemists, Institute of Physics, Institute of Struc tural Engineers, Association of Scientific Workers, Institution of Mechanical Engineers and the Institute of Chemistry. The deputation clearly had as its object the views expressed in the leading article in NATURE of July 18.

Statistical ('Quality') Control of Production

SIR CHARLES DARWIN, director of the National Physical Laboratory, was the principal guest at the July meeting of the Scientific Instrument Manufacturers' Association of Great Britain, and spoke after luncheon about the use of statistical methods in the control of machine-production. He described some developments of these methods in mass-production in the United States; and the encouraging practical outcome of the discussion on the subject in April held at the Institution of Mechanical Engineers (see NATURE, May 23, p. 573). 'Quality control', as contrasted with simple 'limit' gauging (go or not-go) and the rigid specification of tolerances, applies the principles of the law of errors towards obtaining advance information of the tendencies in course of machine production, and towards correlating the users' requirements with manufacturing economy. Sir Charles gave impressive illustrations of practical results following adoption of this method.

Makers of scientific instruments are not ordinarily affected by considerations introduced by mass production methods; and there was some tendency to question the applicability of statistical method to quantities such as they usually handle. There was, however, considerable interest in its possibilities in regard to the quantities in which they are now making many military instruments. Several speakers attached much importance to letting the operatives see their working charts, describing the stimulus value of bringing home to the workers the results of the work they are doing. There was a suggestion that the service inspection departments stand in greater need of education in statistical principles than do the manufacturers; but the speaker was reassuring about official sympathy in this direction.

British and Russian Naturalists

THE following telegram was received by the Linnean Society of London from the Moscow Naturalists' Society on July 11: "Linnean Society, London. Council of Moscow Naturalists of which Charles Darwin was honorary member has been instructed by its members assembled at meeting in commemoration of centenary of appearance of his Origin of Species to convey their ardent greetings to Linnean Society. In midst this great ordeal which has fallen to lot of democratic countries and of science Moscow Naturalists' Society oldest scientific society in Soviet Union pays reverent tribute to memory great scientist and humanist and firmly believes in early victory of our countries over Hitler tyranny". Academician Alexander Fersman, Professor Serge Ogneff, Professor Vera Varsanofieva (vice-presidents), Professor Serge Lipshitz (Secretary).

The following telegram was sent by the Linnean Society of London in reply on July 16: "Moscow Naturalists' Society, Moscow. The Linnean Society of London heartily reciprocates your friendly greetings and joins in tribute to memory of Charles Darwin most illustrious member on our roll. The magnificent resistance of the Russian people to Nazi aggression has aroused deepest admiration in our country. We share your confidence in early victory of the United Nations and are with you to the end". E. S. Russell (President).

Polish Science and Learning

ATROCITY follows atrocity so rapidly on the continent of Europe that public conscience is only momentarily aroused by any fresh crime made in the name of the Nazi 'New Order' in Europe. The Polish nation has been the special object of German fury, and Polish scholars and men of science in exile feel it is their duty to remind others of what is at stake. *Polish Science and Learning*, which resembles *Nauka Polska* (Polish Science) that recorded during 1919–39 the trends and progress of general and natural science, has been founded by a group of Polish savants now working in Great Britain and representing seventeen universities, academies and research institutes. Its object is to record the continuation of their researches as well as to direct attention to events in their unhappy country, where all universities and colleges and indeed all educational establishments above primary schools have been closed. Of the hundreds of periodicals covering all branches of pure and applied science, not one is left. Practically the whole of the rich Polish literature is denied to the nation to-day. In 1940 the Germans issued a 49-page list of books banned from all libraries in Poland. It included the names of 1,500 authors and the number of works cited was about five thousand. Meanwhile, Polish university life is being maintained in Britain and the United States. Many professors and lecturers are carrying on researches at British universities and institutions, and an imposing list of publications has already resulted. In addition, a complete Polish Medical School was established at Edinburgh in 1941. Also, an autonomous Polish Institute of Science and Learning has been set up in New York to act as a publication centre and to arrange courses of lectures and discussions. There is thus a continuity of Polish scientific work, and a body of savants is ready to resume duties at home when their land is liberated.

Cotton Research in East Africa

THE report of the administrative council of the Empire Cotton Growing Corporation submitted to the twenty-first annual general meeting on June 2 refers to a report by the Scientific Advisory Committee which outlines a scheme for the establishment by the Corporation of a Central Cotton Research Station in Uganda. Careful examination of the work being done by the present experiment stations has confirmed the view expressed in last year's report as to the value for the Empire of such a station in East Africa, at which fundamental scientific investigations could be carried out arising from practical problems that confront cotton-growing in those Dominions and Colonies in which the crop is cultivated on a commercial scale. The functions of such a station are defined as to carry out research on problems of cotton growing, especially on those of common interest to several territories. Such work should have a practical bearing on cotton production, and cotton should be treated as an element in peasant agriculture, compatible with food production, the prevention of erosion and the maintenance of soil fertility. Its functions would also include the co-ordination of certain activities of the Corporation's stations elsewhere in Africa, and if requested, of stations working on cotton and staffed by the Colonial Agricultural Service.

Though no distinction should be drawn between fundamental and immediate research work, an orderly division should be made between general and local problems, the former being incorporated in the programme of the research station and the latter suggested for investigation at other stations. The research station should collaborate with the latter in the particular application of general results to local conditions, and its work should also be framed so as to be complementary to that of the Departments of Agriculture. The Corporation hopes to be able to provide the finance necessary for the recurrent expenditure of the research station, and the Colonial Office has been asked to approve in principle a grant being made after the War from the Colonial Research Fund to cover the capital cost of the station in land, buildings and equipment. The report of the Council also includes some notes on the work during the year of the Genetics Department and the Physiology Department of the Research Station, Trinidad, and on research work carried out at the Universities of Cambridge and Manchester, the Imperial College of Science and Technology, and the Rothamsted Experimental Station.

Folk-lore Treatment of Sneezing

THE March issue of the *Bulletin of the History of Medicine* contains an interesting article on contemporary folk-lore treatment of sneezing by Dr. Leo Kanner of Baltimore, who classifies the folk-lore remedies for this condition in the following categories: (1) suggestions, general or specific, of the healers whom the patient should consult; (2) metaphysical cures and prayers, mental equilibrium and magnetic treatment; (3) cure through fright; (4) external remedies, such as pressing and rubbing; (5) local applications to the nasal mucous membrane; (6) spraying, inhaling, snuffling, smelling and gargling; (7) exhaling; (8) remedies *per os*; (9) complicated recipes; and (10) hygienic and dietetic measures. Dr. Kanner comes to the conclusion that contemporary folk-lore, despite its apparent simplicity, is a highly complex mixture of a number of different ingredients which consist of the retention of beliefs and practices dating back from the earliest times; borrowed but not fully understood gleanings from current scientific medicine; survival of methods which were part of the repertory of practitioners two or three generations ago; and references to present-day healing cults.

Prophylaxis of Malaria in Argentina

IN a recent paper (*Bol. Of. San. Panamericana*, 21, 233; 1942) Dr. Hugo J. D'Amato, secretary of the National Department of Hygiene at Buenos Aires, states that during 1940, and especially from January until April, there was a decided increase in the number of cases of malaria in North Argentina, where the disease is endemic, with the exception of those areas protected by the public health services, thus proving the efficiency of the methods applied. More than 170,000 patients were examined by the services of the National Department of Health and more than 20,000 in the provincial and municipal institutions; this is an increase of 5 per cent on the figures of the previous year. *P. falciparum* accounted for 33 per cent of the infections as compared with 12 per cent for the previous year. In 1940, 11,200 more patients were treated than in 1939 and more dispensaries were opened. About 1,600 kgm. of quinine are distributed every year, health education is carried out intensively, nearly 350,000 pesos are set aside yearly for preventive work, and private donations add 50,000. In 1940, 30,250 houses were visited, in 8,210 of which mosquitoes were found, chiefly *Anopheles pseudopunctipennis* and also a few *A. arsimaculatus*, *A. œgyritarsis*, *A. perizi* and *A. albitarsis*. Drainage, filling in, and other sanitary procedures were carried out on a large scale. More than 200,000 litres of petroleum and 70,000 kilos of Paris green were used.

Public Health in Chile

THE March issue of the *Boletin de la Oficina Sanitaria Panamericana* contains a survey by Dr. Pedro Aguirre Cerda, president of Chile, on the present state of public health in the Republic. Since the end of 1939 the country has been free from epidemic disease with the exception of one or two sporadic cases of typhus. Whereas, in 1938, 70 per cent of the conscripts serving in America contracted malaria, in 1940, there was not a single case. Special attention has been given to maternal and child welfare, and it is hoped that the present high infant mortality will be considerably reduced in two or three years. A scheme of medical attention is being planned to provide for mothers from the onset of pregnancy and for children from birth until they are able to work. The acute housing problem is being solved by providing hygienic and comfortable homes for workers at a low cost. Popular restaurants served approximately 2,000,000 meals to 1,000,000 persons in 1939, and 4,000,000 meals to 1,200,000 in 1940; 5,000,000 pesos have been allocated to aid deserted mothers and children as well as other handicapped persons.

Earthquake in Spain

AN earthquake was felt in Granada in southern Spain early on July 12. According to human perception, the shock lasted for about ten seconds, although no damage or casualties have been reported. The epicentre was estimated to have been some eighteen miles from the city, and a slighter aftershock was felt a few minutes later. Since earthquakes show a marked tendency to recur in areas once affected, it is not surprising that earthquakes such as this one should occur. In southern Spain such shocks and smaller tremors are by no means infrequent, though probably one of the largest earthquakes to occur in Spain was that on November 1, 1755, near Lisbon, the written records of which were studied by the late Dr. C. Davison.

Earthquakes in South America

THE United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has determined the epicentres of two recent South American earthquakes. From seismographic reports from twenty-two observatories, the epicentre of the earthquake of May 14 at 2h. 13·3m. U.T. provisionally turned out to be near lat. 1° S., long. 79° W. This is near the town of Riobamba, in Ecuador. From reports from five stations, the provisional epicentre of the earthquake of May 14 at 8h. 39.0m. U.T. turned out to be on the bed of the Pacific Ocean, off Tumaco in Colombia. Both epicentres are in well-known seismic regions.

Earthquakes in New Zealand

DURING April 1942, ten strong distant earthquakes were registered on the seismographs situated in various parts of New Zealand (New Zealand Seismological Report, Provisional Bulletin No. P-122). Additionally, there were twenty earthquakes which were felt in some part of the islands during the month. The strongest were on April 25 at 4h. 53·2m. U.T., which was felt with intensity 6 on the Rossi-Forel scale in the southern Hawke's Bay and Manawatu regions, and on April 26 at 00h. 26·3m. U.T., which was felt with intensity 5 (R.F.) in the neighbourhood of Upper Takaka. Other regions affected were Cook Strait and Christchurch, April 1, Hastings, April 2, Rotorua, April 8, Wairoa, April 18, Naseby, April 28, and Tokaanu, April 30. Minor activity was also recorded on several days at the observatories of Wellington, Christchurch, Auckland and Arapuni.

The strong New Zealand earthquake of June 24 which occurred at about 11.18 p.m. (local time) in the neighbourhood of Masterton (NATURE, July 4, p. 18) was strongly recorded with a full suite of pulses at Kew Observatory. According to the provisional interpretation of the seismogram at Kew, the vertical record received $ePKP_1$ at 11h. 36m. 32s. U.T. on June 24. On this record a maximum ground movement at Kew of 86 μ was attained at 13h. 04m. 15s. U.T. and the recording finished at about 17h. U.T.

Electrical Equipment of Buildings

THE Institution of Electrical Engineers has just issued recommended War Emergency Relaxations of the Regulations for the Electrical Equipment of Buildings (11th Edition), copies of which are available from the Institution free of charge, except where a number of copies is required. Regulation No. 304 relating to voltage-drop is amended, and the current ratings of certain cables are increased. The current-rating tables affected are Nos. 5 to 9 inclusive and 16. Two new tables, 5(A) for small single-core cables of earthed concentric wiring, and 10(A) for mineral insulated cables of 0·007 sq. in. cross-sectional area and above, are now added. Table 10(A) takes the place of Tables 10, 11 and 12 referred to in clause 302(B) for the cables in question. The purpose of the relaxations is to economize in materials.

Beit Memorial Fellowships for Medical Research

AT a recent meeting of the Trustees of the Beit Memorial Fellowships for Medical Research, Dr. A. N. Drury, Huddersfield lecturer in special pathology in the University of Cambridge, was appointed to the Advisory Board in succession to the late Prof. A. J. Clark. The Trustees noted with pleasure the election this year of three past fellows to the fellowship of the Royal Society, namely, E. Hindle (junior fellow, 1910–12, and senior in tropical medicine, 1927–33); F. M. Burnet (1926–27) and A. R. Todd (1935–36). Of the twenty-eight present fellows, there are now fourteen seconded for whole-time war-work.

The following elections have been made, with permission for each fellow to be seconded at any time for war duties: *4th Year Fellowship* (£500 a year). Mr. E. G. L. Bywaters, to continue his studies of crush injuries in relation to kidney function, at the British Postgraduate Medical School, London. *Junior Fellowships* (£400 a year). Dr. D. Herbert, to study the biochemistry of toxoids for active immunization against gas gangrene, at the Dunn Biochemical Laboratory, University of Cambridge. Dr. F. W. Landgrebe, to study the separation of posterior pituitary hormones, and their clinical uses, at the Medical School, University of Aberdeen.

The Night Sky in August

THE moon is new on August 12d. 02h. 28m. U.T. and full on August 26d. 03h. 46m. The following conjunctions will occur during the month: Aug. 2d. 04h., Venus in conjunction with Jupiter, Venus 0·3° S.; Aug. 6d. 09h., Saturn in conjunction with the moon, Saturn 3° N.; Aug. 9d. 05h., Jupiter in conjunction with the moon, Jupiter 4° N.; Aug. 9d. 21h., Venus in conjunction with the moon, Venus 4° N.; Aug. 13d. 15h., Mars in conjunction with the moon, Mars 0·7° N.; Aug. 19d. 13h., Mercury in conjunction with Mars, Mercury 0·01° S. Mercury is in conjunction with the sun on Aug. 2 and is an evening star at the end of the month. Venus is still a morning star. Mars is too near the sun for observation. Jupiter is a morning star in the constellation of Gemini. Saturn is a morning star north of Aldebaran. Occultations of stars brighter than magnitude 5 are as follows: Aug. 6d. 01h. 41·9m., 71 Tauri, R.; Aug. 6d. 01h. 58·8m., θ^2 Tauri, D.; Aug. 6d. 02h. 09·8m., θ^1 Tauri, D.; Aug. 6d. 02h. 44·0m., θ^1 Tauri, R.; Aug. 6d. 02h. 54·9m., θ^2 Tauri, R.; Aug. 30d. 00h. 49·4m., ν Piscium, R.

There will be a partial eclipse of the sun on Aug. 12, invisible at Greenwich. On Aug. 26 there will be a total eclipse of the moon, partly visible at Greenwich. The circumstances of the eclipse are as follows:

Moon enters penumbra Aug. 26d.	01h.	01·7m.
„ „ umbra	02	00·5
Total eclipse begins	03	00·9
Middle of eclipse	03	48·0
Total eclipse ends	04	35·0
Moon leaves umbra	05	35·3
„ „ penumbra	06	34·0

The Perseid meteor shower will attain its maximum during Aug. 10–12.

Announcements

PROF. J. W. H. EYRE, emeritus professor of bacteriology, University of London, has been elected president of the Royal Institute of Public Health and Hygiene in succession to the late Sir Thomas Oliver. Prof. Eyre was senior vice-president and one of the founders in 1903 of the Institute of Hygiene, which amalgamated in 1937 with the Royal Institute of Public Health to form the present Institute.

AT a meeting of the Yorkshire Federation of Museums and Art Galleries, recently held at Huddersfield, Mr. T. Sheppard, formerly director of the Museums at Hull, was elected an honorary life member, "in recognition of his services to the International museum movement, and to the Yorkshire Federation in particular".

THE following appointments have been made in the Agricultural Department of the University of Leeds: Mr. J. B. Mackinson, honorary assistant to the Veterinary Investigation Officer; Mr. P. H. Brown, lecturer in horticulture; Miss E. M. Parker, assistant lecturer in agricultural bacteriology; Miss Margaret W. Crunan, instructor in rural domestic economy; Miss Elizabeth Darley, temporary instructor in poultry husbandry.

Number of Primes and Probability Considerations

SEVERAL months ago Lord Cherwell[1] directed attention to an apparent paradox which arises if one attempts to use probability considerations to determine the asymptotic density of prime numbers. The argument is this: The probability that a large number is not divisible by a prime p is $1 - \frac{1}{p}$. If we assume that such probabilities are independent for all pertinent trial divisors, we obtain as the density of primes near N^2 the value $\prod_{p<N}\left(1 - \frac{1}{p}\right) \sim \frac{1}{e^{\gamma} \log N}$; the correct value, however, is $\frac{1}{2 \log N}$.

It is, of course, possible for mathematicians to dismiss such a question at once as unworthy of any consideration[2]. On the other hand, there are probably few physicists who would not feel at first sight that this is an eminently reasonable—perhaps even the only 'really' reasonable—approach to the problem, "How likely is a number near N^2 to be prime?". This feeling carries with it an obligation to try to account for the difficulty.

As Lord Cherwell remarks, the discrepancy must come from the fact that the probabilities are not independent. That they *may* not be independent is obvious. It can easily be shown that $\prod_{p<N}\left(1 - \frac{1}{p}\right)$ is the *mean* density of numbers not divisible by any prime less than N, in the sequence of numbers 1, 2, 3, . . . $\prod_{p<N} p$; but numbers near N^2 are in a highly special position—very near the beginning—in this long sequence, so that there is no basis for identifying this particular *local* density with the mean density.

Now, the density near N^2 of numbers which are divisible by p but not divisible by any smaller prime is $1/p$ times the density near N^2/p of permissible quotients: that is, of numbers not divisible by any prime less than p. If $p > N^{2/3}$, such quotients must themselves be prime; for $N^{1/2} < p < N^{2/3}$, they may be either single primes or products of two primes, each $\geqslant p$; and so on.

Thus the density of primes near N^2 must be equal to: [density near N^2 of numbers not divisible by any prime less than $N^{2/3}$] minus $\left[\sum_{N^{2/3}<p<N} \frac{1}{p}\right.$ (density of primes near $\left.\frac{N^2}{p}\right)\Big]$. If we take $\prod_{p<N^{2/3}}\left(1 - \frac{1}{p}\right)$ as a rough value for the first term, and evaluate the second by using the formula $\frac{1}{\log u}$ for the density of primes near u when $N^{2/3} < u < N^{4/3}$, we get

$$\prod_{p<N^{2/3}}\left(1 - \frac{1}{p}\right) - \int_{N^{2/3}}^{N} \frac{du}{u \log u \log \frac{N^2}{U}} =$$

$$\frac{3e^{-\gamma} - \log 2}{2 \log N} = \frac{0{\cdot}9913.}{2 \log N}$$

By replacing the assumption that the probabilities are independent by an asymptotically correct procedure in part of the range, we have reduced the error in the result to less than 1 per cent.

If the assumption that the probabilities are independent is used only as far as $N^{1/2}$, the density of numbers eliminated by trial divisors between $N^{1/2}$ and $N^{2/3}$ is given by a double integral. The result obtained for the density of primes near N^2 is $\frac{1}{2 \log N}$ times the factor

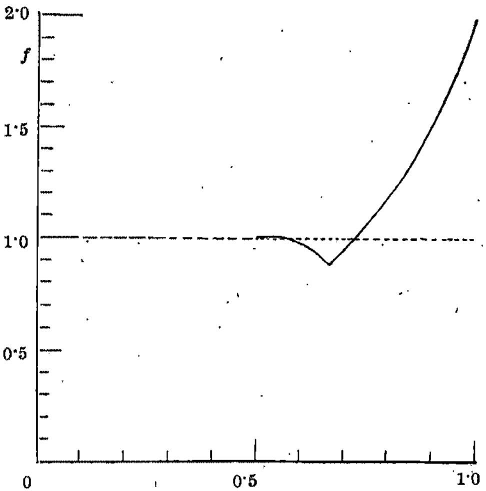
$$4e^{-\gamma} - \log 3 - \log 2 \,.\, \log \tfrac{3}{2} + \tfrac{1}{2} \sum_{k=1}^{\infty} \frac{1}{k^2 \cdot 4^k} =$$
$$1{\cdot}0000050.$$

It seems that the breakdown of the assumption that the probabilities are independent becomes considerable only for the larger trial divisors, and that we have a correct procedure to replace it there.

Another way of expressing the situation is as follows: The probability that a number n is divisible by a prime p is $1/p$, if concerning n we know only that it is large compared with p. If we know that n is *near* N^2 and *not divisible by any prime smaller than* p, then the probability that n is divisible by p is not $1/p$, but f/p. For $N \gg 1$, the factor f is a function of $\xi = \log p/\log N$; it vanishes for $\xi > 1$, and for $\xi < 1$ it can be calculated by using the sort of considerations described above. We find that

$$f(\xi) = \frac{2}{(2 - \xi)\,[1 + \log (2 - \xi) - \log \xi]}, \quad \tfrac{2}{3} < \xi < 1;$$

for $\frac{1}{2} < \xi < \frac{2}{3}$ a single numerical integration is required to determine f; and for smaller values of ξ the calculation is more complicated and has not been carried through.



The behaviour of the function f between $\xi = \frac{1}{2}$ and $\xi = 1$ is shown in the accompanying figure, and makes it seem extremely plausible that f is almost exactly unity for $\xi < \frac{1}{2}$—that is, that the trial divisors smaller than $N^{1/2}$ are practically independent in their action on the numbers near N^2. Since $f(1) = 2$, the last and largest of the trial divisors finds roughly twice as large a proportion of victims among the survivors of the previous trials as it would in a virgin population.

The considerations given here are, of course, of no value as a proof of the $1/\log u$ distribution of primes.

That theorem remains the property of students whose approach is more subtle than "probability considerations". The only use of the above remarks is to satisfy those who feel that the failure of the probability argument needs some elucidation, by showing how the factors do indeed tend to "avoid one another". I am grateful to Lord Cherwell for directing the attention of readers of NATURE to this question, and hope that he will find this answer satisfactory.

[1] NATURE, 148, 436 (1941).

[2] Hardy and Littlewood, *Acta Mathematica*, 44, 36–37 (1923), especially footnote 4, p. 37.

I AM grateful to Prof. Furry for his sympathy with the outlook of a mere physicist and for the light he has thrown upon this matter. Prof. E. M. Wright, some months ago, sent me privately a proof on somewhat similar lines that the probabilities could not be independent for primes greater than $n^{0 \cdot 76}$. Prof. Furry has carried the process a step further and shown the degree of divergence.

The mode of attack is not unlike one which I had pursued earlier without success. If ε is small compared with n, there seems no apparent reason why the density of composites containing prime factors less than n should not be the same in the neighbourhood of $n^2 + \varepsilon$ as it is in the neighbourhood of n^2. But in the neighbourhood of $n^2 + \varepsilon$, over and above the composites whose smallest prime factors are less than n, we must take account of the composites whose smallest prime factors lie between $\sqrt{n^2}$ and $\sqrt{n^2 + \varepsilon}$. Pursuing this line of thought, the following equation for the number of primes in the neighbourhood of z seems to emerge:

$$f'(z)_{z=n^2} = -\left(\frac{f(z)}{2z}\right)^2_{z=n}.$$

At first sight this seems promising since it is obviously satisfied by $f(z) = \frac{1}{\log z}$. But unfortunately it is also satisfied by the expression $f(z) = \frac{a}{z^{a/4}}$ where a may have any value, and I have not so far succeeded in finding any simple argument which excludes solutions of this type.

CHERWELL.

Oxford.

Relationships of some Primitive Tetrapods

IN the final draft of an earlier letter[1], the occurrence of Diadectes in the late Stephanian was omitted by mistake. A misprint also needs correction, the index to reference 7 (par. 5, line 8) should follow "Moodie" (same line).

The opening sentence of par. 4 requires further comment. A somewhat similar structure is found in the Lower Carboniferous (Viséan) Otocratia, from the Burdie-house Limestone of Midlothian[2]. This skull has the otic notch nearly closed, and with one exception the skull-pattern (so far as it is known) is remarkably similar to that of Microbrachids and primitive Captorhinomorphs. The exception is the larger size of the postparietals, which exclude the parietals from contact with the tabulars. The structure of the homologous region in Osteolepids, Elpistostege, Ichthyostegids and most Stegocephalia is similar and undoubtedly represents the primitive condition. In Anthracosaurs, Microbrachids and early reptiles the postparietals are smaller, and the parietals and tabulars meet; in these forms the posterior part of the skull shows great shortening. It is therefore possible to regard the difference in structure between Microbrachids and Otocratia as due to increasing specialization of the former, for which Otocratia could thus provide a suitable morphological ancestry. In these forms the broad contact of the parietal and postorbital separates the supratemporal from the postfrontal, there is no separate intertemporal, and the orbits lie in front of the middle of the skull.

Otocratia is remarkably similar in skull-pattern to the Ichthyostegids and Elpistostege, except that its otic notch is obliterated by downward rotation of the tabular. The structure in Otocratia regarded by Watson as an internal nostril is too anteromesially placed, and appears to be the anterior palatal vacuity, bridged (as in some Osteolepids) by a strong median bar from the premaxillaries. The "advanced" features noted by Watson in this genus are found also in Ichthyostegids[3], and form indeed a very sharp contrast to early Embolomeres. I regard Otocratia as probably derived from Ichthyostegids. Its structure is suitable for the morphological ancestry of the Dinantian Adelospondyls described by Watson[2].

It is noteworthy that the earliest-known Embolomerous types (Loxommoids and Anthracosaurs) come from strata of Namurian age, while Otocratia, the Adelospondyls just mentioned and an undetermined "Lepospondyl"[3] are of late Dinantian (Viséan) age; the last-named is the earliest known 'Amphibian' skeleton except the Ichthyostegids. The vertebræ of these earliest forms have large centra and small or absent intercentra, as in Microbrachids and Captorhinomorphs. Currently accepted views on vertebral evolution seem to require adjustment.

I suggest tentatively that the Ichthyostegids and Otocratia, which are quite distinct from the commoner Labyrinthodont groups, are early members of a group of primitive Tetrapods which gave rise to the typical Microsauria and to the Diadectomorph and Captorhinomorph reptiles. I hope to discuss the implications of these observations and suggestions elsewhere.

Narcotic for Marine Invertebrates

THE following method is cheap and simple, and gives excellent results with such soft-bodied marine animals as have been tried (Polychætes, Doris, Priapulus, Nemertines, Ascidians). Make up 80 gm. of crystalline magnesium chloride in a litre of tap water. Immerse the animals in it. In one to four hours they will be relaxed and expanded. Add strong formalin to the magnesium solution; when they are dead, transfer to any desired fixative or preservative.

The solution is isotonic with sea-water, has apparently no irritating effects, and appears to be better and easier to use than menthol, cocaine, etc. In

Arenicola, at least, the tissues are undistorted and the material can be used for histological purposes.

The magnesium solution narcotizes but does not kill, at least for many hours. The narcosis can be rapidly reversed by transferring the animals back to sea-water.

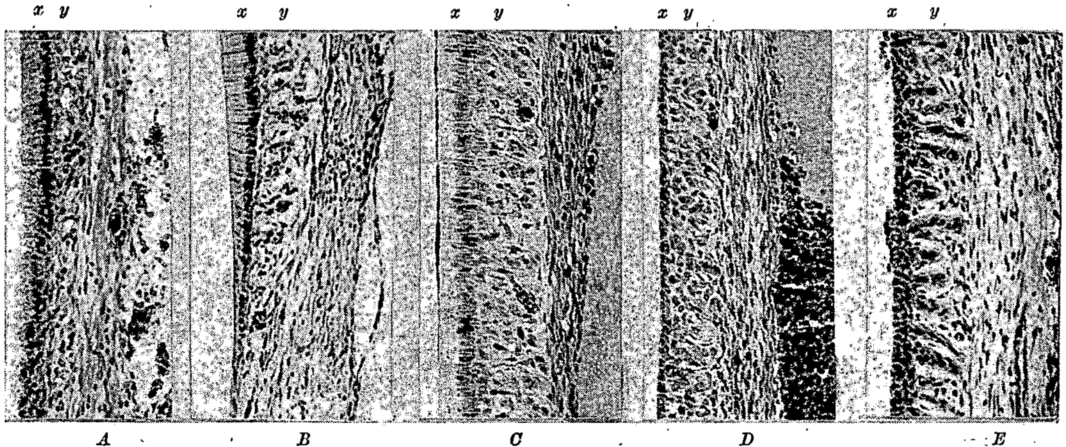
Enamel Organ of the Rat's Incisor Tooth in Vitamin E Deficiency

Davies and Moore[1] have pointed out that rats on a diet deficient in vitamins A and E suffered from a secondary vitamin A deficiency as evidenced by a disappearance of the vitamin from the liver; and also by a whitening of the incisor teeth, an effect which occurs in prolonged vitamin A deficiency[2] and was prevented by vitamin E dosage. Through the kindness of Dr. H. E. Brink, Department of Physiology, University of Stellenbosch, who has been working on vitamin E deficiency, I have been able to examine the incisor teeth of three female rats which had been on a vitamin E deficient diet[3] for 167 days from weaning. They had shown complete resorption of ambryos and the characteristic paralysis of the hind legs had just set in. The incisor teeth had the normal orange colour.



LONGITUDINAL SECTIONS OF THE MID-REGION OF THE ENAMEL ORGANS OF RAT'S TEETH.
In all sections the enamel has been lost during histological decalcification. *x*, ameloblasts, *y*, epithelial papillæ. (× 128)
A, *B*: Upper incisor teeth of two female rats 167 days on a diet deficient in vitamin E.
C, *D*: Two normal female rats 239 days old. *E*: Rat 150 days on a diet deficient in vitamin A.

Longitudinal sections of the upper incisor teeth were cut and stained with hæmatoxylin and eosin. On microscopical examination, an abnormal degeneration was found in the enamel organ, which is illustrated in the accompanying photomicrographs (*A*,*B*).

It should be pointed out that in the rat's incisor, the enamel organ, and especially the ameloblasts, regress as they get older, having an average life of 50 days[4]. In young rats with rapidly growing incisors, the ameloblasts are still columnar when they reach the gingival margin, since they take only 25 days to get there; but in adult rats, the incisor grows more slowly and the ameloblasts regress in the anterior third of the tooth. If the tooth grows faster than usual, as can be caused by cutting off the exposed part, then the accelerated growth causes the ameloblasts to remain columnar up to the gingival margin[5], and conversely, if growth is slowed, the ameloblasts regress earlier. The rest of the enamel organ also regresses in a manner comparable to that of the ameloblasts. The epithelial papillæ, which are very prominent in the middle third of the tooth, gradually shrink, but can still be seen in the anterior third of the enamel organ.

The incisor teeth of the three vitamin E deficient rats showed a premature and abnormal degeneration of the enamel organ. This was found in the centre of the middle third of the tooth. One rat showed a disappearance of the epithelial papillæ and a shrinkage of the ameloblasts to an ill-arranged cubical layer (*A*) and the other two rats showed a sudden disappearance of all layers of the enamel organ, which was replaced by fibrous tissue (*B*). Comparable sections of the same part of the enamel organ from two normal female rats are given in *C*, *D*. These rats were 239 days old. These sections illustrate the degree of variability found under normal conditions in this area. In *C*, the ameloblasts are still distinctly columnar, while in the other (*D*) they have regressed to a considerable extent. In both, however, the epithelial papillæ are quite large and pronounced. The diet deficient in vitamin E used by Dr. Brink was not deficient in vitamin A, and thus no whitening of the teeth was seen, though it is true that these rats were younger than those reported by Davies and Moore. That no deficiency of vitamin A occurred is seen from a comparison of *A*,*B*, the latter being from the corresponding part of the enamel organ of a rat 150 days on a diet[6] deficient in vitamin A. This shows the characteristic atrophy of the ameloblasts and also the shrinkage of the epithelial papillæ which are found in this condition and which are quite unlike the changes found in *A*,*B*.

It would thus appear that rats on a diet adequate in vitamin A but deficient in vitamin E developed an atrophy of the enamel organ of an unusual type, unlike that caused by any other vitamin deficiency and possibly specific to vitamin E deficiency. It is of interest that vitamin E deficiency, apart from producing a dental change from secondary A deficiency as reported by Davies and Moore, may also itself cause a degeneration of quite different kind in the same area.

Selective Excitation of Spectra by the High-Frequency Discharge

IN a series of preliminary investigations on the excitation of spectra by the high-frequency discharge, several interesting phenomena connected with intensity distribution have been observed, some of which have already been reported[1]. Further work indicates that these consist essentially in a redistribution of intensity among different band-systems of a diatomic molecule (that is, among different electronic energy levels) or among atomic energy states of different multiplicities. Thus the mercury spectrum observed shows that under certain well-defined and reproducible conditions, as for example pressure of gas, frequency of exciting oscillations, etc., only those lines are present which involve triplet initial states. Similarly, again under definite conditions, mainly those band systems of carbon monoxide are excited which involve only the singlet levels.

Keeping the pressure in the discharge tube constant, it is possible in the case of nitrogen, which has been studied so far, so to alter the relative intensities of the first positive and second positive band systems that either one or the other is more prominent at a given frequency of excitation. Thus it is found that with a gas pressure of about 7 mm. there is a critical value ($\sim$ 735 kc./sec.) for the frequency of oscillatory discharge, above which the second positive system and below which the first positive system gains in intensity. This is even more striking visually, the colour of the discharge undergoing a radical change when the frequency is altered.

The phenomena observed are different from those which involve a change of intensity distribution among various bands of a given electronic system. In the simplest case, such an effect will be a consequence of the interaction between the exciting particles and the vibrating nuclei, and has not been established so far in excitation by electrons[2]. In the presence of high-pressure argon[3], and in the afterglow spectrum[4], nitrogen exhibits such a change in distribution of intensity in its first positive band system, but obviously these involve different mechanisms.

The effects observed in the present series of investigations appear to be understandable from a consideration of the different excitation functions characteristic of the initial levels concerned. It has been possible to correlate all the facts with the form of the excitation function wherever this latter is known, thus making it possible to deduce the form of the excitation function in other cases where it may not have been known experimentally. The fact that this is at all possible, however, indicates that in the conditions under which the phenomena occur the following are true to a first approximation:

(1) The pressure in the discharge tube, the frequency of oscillatory discharge and the voltage across the electrodes determine, within a narrow range, the energy available for excitation.

(2) The main process of excitation involves only the emitters in the normal state; excitation through collisions of other kinds appears to be negligible.

Further work is in progress and details will be published elsewhere.

The Problem of the Autonomy of Life

IN his letter published in NATURE of May 16, Prof. Donnan abandons his previous assertion that a potency for producing order resides in the temperature difference between two surfaces. He substitutes the obvious and indisputable statement that an energy disequilibrium is one of the necessary conditions for the production of the specific structure of a living organism. It is, of course, one of the necessary conditions for the production of anything, and so this does not get us any further. The cause of the discrimination of which there is evidence has still to be sought.

I am directing attention to this confusion between the *cause* of a phenomena, and the *conditions* which must pertain, so that the cause may become effective, because this is a very common confusion. It is at the bottom of many other attempts to explain the organic world. Among these is the attempt in Prof. Donnan's letter to do so by invoking photosynthesis. The problem, be it noted, is not merely why there may be in some cases, as Prof. Donnan puts it, "a decrease in entropy". The problem is far greater. It is to discover what in all living substance causes each particle to reach a specified position. *Why does the random incidence of photons lead to anything but a random arrangement of atoms?* The presence of enzymes and chlorophyll in living substance is (like the availability of energy) but one of the many conditions which must be met, so that the discriminating agent, whatever it be, may operate. To attribute discriminating powers to chemical substances would be medieval mysticism, so photosynthesis does not solve the problem. It is itself a part of the problem which we must seek to solve. The very presence of chlorophyll just in those places where it makes photosynthesis possible is another part of the problem.

If, as I have attempted to show, the source of the discrimination is not covered by even the widest definition of the word 'material', we certainly need, as Admiral Beadnell says, a new definition of 'non-material'. This definition must be neither so naive as to include things like electromagnetic radiation, nor so anthropomorphic as to identify non-material with mind. I am hoping that Admiral Beadnell may be among those who can accept my understanding of the term, though it would take too much space to explain it here.

Reginald O. Kapp.

University College,
London.

In my letter of May 16, to which Prof. Kapp refers, I tried to explain that the disequilibrium in question, involving as it does an increase of entropy, was a necessary (though, as I pointed out, not a sufficient) *condition* for the occurrence of the photochemical process, since the latter involves an increase of order and a decrease of entropy. I was careful to point out that the work of the biochemists and plant physiologists was necessary in order to complete the associated complex of conditions and processes which, together with the fundamental condition, constitutes a satisfactory causal analysis of the phenomenon. It will be obvious, I think, to those who have followed the discussion, that what Prof. Kapp now says constitutes a complete travesty of my remarks and demonstrates in the clearest manner that he has failed to understand their meaning.

I am glad, however, that Prof. Kapp has written this second letter, because readers of Nature can now see for themselves Prof. Kapp's method of conducting *his* type of "causal analysis". Let me give one or two examples. The molecules of glucose are found to build up the starch granules in the chloroplasts of a plant cell. Why is this? Because they follow the course *specified* for them. A chemical substance A, when presented in an organism with a mixture of substances B, C, D, etc., is found to combine with B, but not with C, D, etc. Reason for this? Very simple, an unknown X *discriminates*. And so on, *ad infinitum*. This sort of thing is not even "medieval mysticism"; the medieval philosophers and scientists, though suffering in general from a great paucity of facts, were after all good rationalists. Sound and sufficient experiments and sound and sufficient reasoning make science. One cannot buy (or sell) it with the currency of mere words; though you may run a dumb film on captions.

F. G. Donnan.

The Athenæum,
London.

General and Social Biology

The article by Mrs. S. Neville Rolfe in Nature of January 24, p. 90, calls for comment and support. Does it occur to the average man that, except at some schools, everything taught is factual, with definite conclusions? For example, history, geography, grammar, mathematics, physics and chemistry all produce definite results. But when we enter the world in which we live, we are emerging into a world of living and thinking beings. The facts can be ascertained, though often with much difficulty, but the conclusions are too often matters of probability.

It is true that contact with the world teaches some men the peculiarities of social life and human nature. But I cannot understand a nation without any universal training in social biology taking the sound road easily. Their minds have not been trained as they should be.

In administration the defect is obvious, and the difficulties in the way of problems of health are known to many people who have seen them in the Colonial empire. One item—and it is only one item—illustrates. During the War of 1914–18—and there I can speak from personal knowledge of the difficulties—in the British and Dominion troops there were 400,000 reported cases of venereal disease, and in the American Army 340,000, that is, 740,000 in all, with an average absence from duty of five–six weeks and causing a heavy burden on the services. Could this have happened if the military direction had grasped the situation before it developed? Much the same thing may be said of malaria, which took a heavy toll, although Field Marshal Allenby realized the danger and acted accordingly.

How many people realize that there are 650 million people suffering from malaria—about 1 in 3 of the population of the world. But the very good medical education in the universities is directed chiefly towards the treatment of disease. The prevention of disease and the maintenance of health, apart from disease, do not receive much attention. The social problems of housing, play space, town planning, etc., scarcely enter the medical curriculum.

Prevention means not only advice but also the active concurrence of everyone. But the general mass of the population, untrained in biology, will continue to make serious mistakes. All universities naturally divide their work into compartments, but the great problems of life very often do not fit into any compartment, and have to be attacked by other methods; hence the need for some form of sociological training.

Higher Algebra

My attention has been directed to an unfortunate error in my review of "The Tutorial Algebra" in Nature of July 11, p. 39. In fairness to the author especially, I should like to correct this. My query, "Is the condition . . . biquadratic?", should have referred to the converse, namely, Does the condition $ac-b^2>0$ hold for every biquadratic having at least two complex roots? My chief concern was to prevent the inference that the roots are all real when $ac-b^2$ is not positive; hence the example. I think the whole point would become quite clear if a brief note were added at the end of the proof of example (2) on p. 510 indicating (i) what happens when H is not positive or equal to zero, and (ii) whether the converse to the theorem proved is true, H being $ac-b^2$.

F. G. W. Brown.

Pyrethrum Sprays

In my article published in Nature of June 27 (p. 720) on "Biological Assay of Insecticidal Sprays", it was stated that a solution of pyrocatechol in ether was recommended as a stabilizer for the standard pyrethrum spray. It must be pointed out that this statement should apply only to a pyrethrum solution used as a standard for comparison in laboratory tests.

A solution of this type, in which ether is employed, would not be suitable for incorporation in a pyrethrum spray intended for commercial use, and the statement concerning its addition does not form part of the standard specification for this type of spray.

MINERAL AND VITAMIN REQUIREMENTS AND THE WAR-TIME DIETARY

At a discussion in the Section of Medicine of the Royal Society of Medicine on May 26 on mineral and vitamin requirements and the war-time dietary, some interesting and important points were brought out, though the subject is very wide and could therefore be covered only in part because in the vast limit it embraces both the qualitative as well as the quantitative requirements.

Mineral Requirements

Dr. R. A. McCance confined his attention mainly to calcium and iron, saying that sodium, potassium, magnesium, zinc and phosphorus and the 'trace elements' such as copper and manganese can be left to themselves. He opened by stating that to maintain ourselves in perfect health we have to *absorb* just as much calcium, phosphorus and other mineral elements as before the War; even then there was a belief that calcium and iron were deficient. In the modified and planned war diets, there is now plenty of milk for children but little for adults. The calcium and iron intake is maintained by the 85 per cent extraction loaf which has 2–3 times as much iron as in white bread. The problem is whether these two minerals are as well absorbed as in peace-time. In an investigation by Drs. McCance and Widdowson upon human subjects (taking more than fourteen months) the calcium proved to be less well absorbed when brown 92 per cent extraction flour was substituted for white flour in the diet. The same has been found more recently with iron, though the results need some repetition. The nature of the factor responsible for depression of absorption has emerged as the result of much research. E. Mellanby earlier stressed the presence of a rachitogenic factor in some cereals, especially oatmeal. Much later (1934) Bruce and Callow suggested that this might be inositol hexaphosphoric acid, a compound present in the outer parts of the cereal grains. In 1939 Harrison and Mellanby showed that addition of sodium phytate to puppies' diet led to rickets. It was left to McCance and colleagues to prove that the addition of sodium phytate to white bread depressed absorption of calcium and magnesium more than the brown bread diets, some subjects even excreting more calcium in the fæces than they took in the food (due to fixation of calcium in some of the intestinal secretion). Removal of phytin in bread is possible on the experimental scale though impracticable commercially, and does not completely reduce the error in absorption. Nor does vitamin D in physiological doses improve the absorption of calcium in adults. The cheapest and simplest way to counteract the action of the phytic acid is to add calcium as calcium carbonate to precipitate the phytic acid and so leave the remaining 'calcium' available for absorption. In the 85 per cent loaf this is about half the amount of phytic acid present in the '92 per cent'. Dr. McCance considers that the physiological arguments for addition of calcium (as calcium carbonate) to the 85 per cent loaf are very strong and that we should have the courage of our convictions and support the addition to maintain adequate calcium absorption. A similar argument holds for iron.

Prof, R. A. Peters in a short communication produced X-ray pictures by Dr. Kemp, of Oxford, to demonstrate that in a man of 52–53 years the addition of calcium carbonate to the maximum amount recommended by Dr. McCance and adopted by the Medical Research Council (namely, 14 oz. per 280 lb. flour) to 85 per cent extraction bread has produced no signs either of calculus or calcification of the femoral arteries. His family has lived on this bread (+ chalk) for thirteen months with no noticeable ill-effects, as indeed would be expected, when it is realized that the addition is only 1/20 oz. calcium carbonate in 1·3 lb. bread.

Dr. Murray Scott discussed minerals from a practitioner's point of view; as chairman of a local borough committee on bread, he has been trying to get evidence of deficiencies attributable to faulty diet, etc. In his part of the country medical and obstetrical opinion asserted there is increasing anæmia; examination of miners' wives showed reduction in hæmoglobin, and indicated that the miner frequently eats all the meat and cheese in the family ration. For several years second-year medical students at Leeds have estimated their own hæmoglobin; for the six years before the War the numerically largest group has always been in the 100–105 per cent hæmoglobin division. Last year, it was the 90–95 per cent division. A careful survey of prices in August 1941 showed that for an active man a complete optimum diet could not be purchased for less than 14*s*. a week, and for sedentary workers 11*s*. per week. Since the rationing of meat, bacon, eggs and cheese reduces the intake of iron to 1–2 oz. a day from this source, there is a theoretical expectation of increasing anæmia among the poorer half of the nation. The change to 85 per cent extraction meal will increase the iron of the diets for most people by about 2·5 mgm. a day, without disturbing the supply of calcium and phosphorus which comes from the milk, though the use of some of the wheatings in the new flour will deprive pigs and poultry of part of their present supply. In considering possible disadvantages of 85 per cent extraction flour, Dr. Scott was struck with the apparent discrepancy between the conclusions of Widdowson and McCance's experiments on iron and his general ideas, and wished to have evidence of lack of energy or fall in hæmoglobin. He instanced the case of two adults in his own household, who have eaten entirely wholemeal bread, and yet have hæmoglobins of more than 100 per cent. How does their iron escape the clutches of the phytic acid? In a speculative vein, he asked whether it is possible that prolonged eating of white bread led us to lose a capacity to deal with phytic acid (by phytases or otherwise) which was possessed by our ancestors. In conclusion, he expressed the view that diets contain less total iron than pre-war and that it is important to solve the question of how to increase the available iron in the nation's diet, preferably through bread.

In the parts of the subsequent discussion which bore upon minerals, Dr. H. M. Sinclair pressed for supplements of iron in the national dietary. Dr. A. P. Meiklejohn, in dealing with the question whether the addition of iron to bread was justified upon the evidence so far produced, stated that in a recent survey in Lancashire a random sample of young married women had (low) hæmoglobin limits of about 75 per cent (Haldane scale). Dr. Geoffrey Evans was impressed by the number of persons who had hæmoglobin values below 85 per cent and the obvious improvement by giving iron.

Prof. J. R. Marrack was a sceptic upon the possible 'de-mineralizing' effect of brown bread, as he has always eaten it and been able to play rugby football until he was forty-four. Dr. R. J. Atkins referred to the importance of trace elements and to the presence in soil of elements like manganese which interferes seriously with the absorption of iron. Mr. A. L. Bacharach said that in order to increase the general intake of iron by 5 mgm. per person a day, only eighty tons of iron salts would be needed, and that it was quite easy to carry this out with bread.

Dr. McCance, replying to several points, pointed out that the calcium requirement of individuals shows large variation; some would store calcium on a diet which would lead to loss of calcium in others. This probably explained Prof. Marrack's point. It makes the postulate of an absolute average requirement difficult, and indicates the need for playing for safety.

Summarizing this side of the discussion, there seems to be a general belief in the need for calcium and iron supplements in the diet, in some form, of which bread appears a reasonable medium.

Vitamin Requirements

The requirements of vitamins in the dietary were less thoroughly discussed, the main attention being given to vitamin C. Dr. L. J. Harris urged the existence of subclinical deficiencies. He directed attention to animal experiments in which it could be demonstrated that there is a grading of response to vitamin B_1 between the optimal dosage-level and one giving definite signs of deficiency. It is unlikely that this does not apply to man. He considers that his investigations have shown that levels of nutrition of some vitamins could be judged quantitatively by statistically controlled 'saturation tests' upon groups of people; this must not be taken to mean that he thinks that perfect nutrition is only co-existent with saturation. In the urinary saturation tests for vitamin C, the level of nutrition is judged by the speed with which the urinary excretion with test doses reaches on average a plateau; this takes only one or two days in subjects receiving proper amounts of the vitamin in their diet. Absence of scurvy does not mean necessarily having enough vitamin C. There occurs in man those symptoms of deficiency seen in guinea pigs, namely, diminished growth-rate, failure in the production of new tissues and increased liability to infection. He cited work from German official records in support of the view that extra vitamin C improves the annual gains in weights and height of children and diminishes the incidence of infections (1,600,000 children were given 50 mgm. vitamin C daily in addition to the ordinary war-time diet). In Britain, Glazebrook and Thomson have found less duration of tonsillitis and less disease in naval trainees dosed with vitamin C. Further, Crandon and associates in America and Hunt in Great Britain believe in the value of vitamin C in the healing of wounds; but it is true that the effect upon Crandon himself did not appear until a late stage in his vitamin C deficient diet. On the other side he quoted the view of Zilva (an authority on vitamin C) that even allowing for destruction in cooking, the war-time diet contains enough vitamin C, and also the observations of Fox and colleagues; the latter found that out of 950 miners getting 12–25 mgm. of ascorbic acid twelve developed scurvy, whereas only one out of a similar number getting an extra 40 mgm. developed scurvy.

This point was taken up by Dr. Sinclair, who thought that it created much difficulty in regard to subclinical deficiency, because there was no difference in incidence of infection in Fox's experiments. On the other hand, Dr. Meiklejohn said that long before Dr. Crandon showed signs of vitamin C deficiency he looked a sick man and suffered from vague symptoms of lassitude.

Dr. Harris also referred to the results of some of his saturation tests. Children at a good residentia institution showed consistently higher levels of excretion of vitamin C than those from poorer homes but during the War the level of both groups has fallen; this was more marked in the winter months and justified the decision to set aside supplies of vitamin C for young children.

In relation to this, Prof. Marrack said that in March and April he estimated ascorbic acid in a number of meals in school canteens and British Restaurants, where he found no evidence of excessive destruction in the preparation and cooking. The total ascorbic acid calculated as supplied for one third meals was less than 10 mgm. and for one third was more than 20 mgm. There was evidence that in saturation tests the number of boys saturating on the first day of giving the test dose increased with the average ascorbic acid content of the diet at the school. The highest saturation was in the school which grew abundant early green vegetables, and the choice of vegetables grown is important. It is unwise to trust to raw vegetables.

Dr. Atkins raised some critical points over the saturation tests. He found that in fifty men from the same kitchen differences of saturation occurred according to whether they had their vitamin C tablets before or after breakfast. Further, 40–100 left saturated ten months ago, showed no quicker saturation in a subsequent period of dosing than those previously unsaturated.

In conclusion of his remarks, Dr. Harris said 9 per cent of children in an institution, 15 per cent among urban children, and 18 per cent among village children could be improved by a vitamin A dosing, using a dark adaptation test (Yudkin). Six per cent of school children examined at Cambridge showed riboflavin deficiency (vascularization of the cornea by slit lamp examination). Dr. Geoffrey Evans from his own experience believes in the existence of deficiencies to-day, and stated that cases of acne rosacea with conjunctivitis and mild degrees of keratitis could be improved by giving riboflavin, and cases of fatigue and depression with vitamin B_1. Dr. Magee, striking a critical note, considered that not enough attention had been paid in the discussion to the quantitative requirements and pointed out the great differences between the standard for proteins and minerals which had been arrived at as the result of clear-cut experiments, and the vitamins. For these he regarded the evidence as still more approaching guess-work or speculation.

It is the opinion of the reviewer that the problem of actual quantities of vitamins required could well be discussed again, when more information is available. In regard to this vexed question of 'subclinical deficiency', it must be conceded that evidence is accumulating that levels of saturation of some vitamins may fall to a point which is dangerous in the sense that individuals may be too close to the point of actual deficiency. Such depletion periods will not matter so long as they are only biochemical, provided that they are reversed in time, because there may be still enough vitamin about to run essential biochemical processes. If, however, there is lso the ill-health suggested, it is important; but its ery vagueness must increase the need for caution and for prolonged experiments (taking into account all psychological factors) before coming to a final judgment. It is difficult to see how the state of the individual (as distinct from statistical averages over a group) can be assessed without combining blood estimations with clinical examinations, as Dr. Sinclair nd his colleagues are trying to do. So much for he purely scientific attitude. Meanwhile we are faced with practice in the War. We know from McCance and Widdowson that there is a wide difference in calcium requirements of individuals; we have he League of Nations standards for the earlier vitamin factors, but none for those more recently discovered; we know that even animals are individual in their needs of a vitamin like aneurin. Let us hope that ultimately we may be able to recognize on a scientific basis cases where intake of a special factor must be increased for an individual. For the moment we are left with the dilemma that diets must provide sufficient margin of accessory factors to ensure no physical nefficiency, and we must see that time and valuable foodstuffs (synthetic and natural) are not wasted; fortunately, the latter does not apply to chalk and iron.

R. A. PETERS.

AMINO ACID ANALYSIS AND THE STRUCTURE OF PROTEINS*

By PROF. A. C. CHIBNALL, F.R.S.

IN recent years X-ray crystallographers have made remarkable advances in the interpretation of protein structure, and it is becoming more and more evident that a stage has been reached when their views need to be reconciled with data obtained from accurate amino-acid analysis of the proteins concerned. In 1934 Astbury suggested that in gelatin the residues of glycine and hydroxyproline must repeat at regular intervals along the peptide chain, an idea developed in the following year by Bergmann and Niemann into a general hypothesis that (briefly) the 'frequency' of recurrence of any particular residue must be factorizable entirely by 2 and/or 3, as must also the total number of residues in the molecule. Evidence in its favour was adduced from analytical data for several proteins, including egg-albumin. The hypothesis has been criticized on various grounds, chief among them being that existing methods of analysis are in most cases not sufficiently quantitative to warrant the results being interpreted with the precision needed. What are believed to be quantitative estimations for the bases and dicarboxylic acids in edestin, egg-albumin and β-lactoglobulin have now been obtained.

Edestin.—The analytical data and calculated mean residue weight (115·7) show that the smallest possible unit contains 432 ($2^4 \times 3^3$) residues, and that the number of residues of arginine, histidine, lysine, tyrosine, tryptophan, methionine and cystine are 48, 8, 8, 12, 4, 8 and 3 respectively. On the assumption that the amide-nitrogen can be distributed in such a way that the number of residues of asparagine, aspartic acid, glutamine and glutamic acid are also factors of 432, it can be shown that these must be 27, 18, 36 and 36 respectively. The data lend support to the Bergmann and Niemann hypothesis, but at present there is no evidence that edestin is homogeneous.

β-Lactoglobulin is homogeneous. The analytical data suggest a molecular weight of 42,000, in agreement with physical measurement, but the total number of residues is not factorizable by 2 and/or 3. The Bergmann-Niemann hypothesis is thus not valid. On the assumption that the molecule is one peptide chain, the number of carboxyl groups computed from titration curves is in agreement with the chemical data, but the number of free amino groups is eight more than can be attributed to lysine. The molecule is a system of nine peptide chains, not all of like composition, coupled by linkages involving carboxyl and not amino groups. Imide and thiolester linkages are suggested; the presence of the latter would explain many puzzling features of denaturation.

Egg-albumin is not homogeneous and tells a somewhat similar story. Chemical data suggest a molecular weight of 43,000, in conformity with physical measurements; the Bergmann-Niemann hypothesis does not hold. From titration and other data it is suggested that the molecule is a system of at least four peptide chains having free terminal amino groups, recalling Astbury's deduction that the denatured protein is a pile of four laminæ.

Insulin.—If the excess of free amino groups is a measure of the number of peptide chains, as in lactoglobulin, the molecule of insulin must be a system of eighteen such chains, a striking confirmation of Bernal's prediction from the peaks in the Patterson projection.

Reverting to *edestin*, it has been found that the determination of free amino groups is complicated by edestan formation. It is probable that the submolecule of 50,000 is one peptide chain, though the possibility that it is a system of three peptide chains of unlike composition cannot be dismissed, in which case the allocation of the amide-nitrogen given above would not be justified. Nevertheless, the stoichiometric relationships exhibited by the other residues are sufficiently impressive to warrant the assumption that the constituent peptide chains would be built to essentially the same pattern based on $2^n \times 3^m$, though they might not contain the same number of residues. All other proteins may be similarly constituted. Such views emphasize the need for more work on the isolation and characterization of the partial decomposition products of protein, for much of the evidence hitherto brought forward to support the Bergmann-Niemann hypothesis has been based on inadequate experimental data and has demonstrated nothing more than the hypnotic power of numerology.

---

* Substance of the Bakerian Lecture delivered before the Royal Society on July 16.

TIMBER-SEASONING KILNS

TWO leaflets have recently been issued by the Forest Research Institute, Dehra Dun, India, on the subject of timber seasoning kilns by M. A. Rehman, Utilization Branch (For. Res. Inst. Public. Vasant Press, Dehra Dun, 1941–42). Leaflet No. 11, "Types of Timber Seasoning Kilns suitable for drying Indian Woods" (1942), describes briefly the various types of seasoning kilns which have been designed or tested by the Forest Institute. It was due to the position in which we found ourselves during the last War in the matter of timber supplies, especially perhaps in the demand for, and absence of, seasoned timber for the increasing aeroplane construction, that led to the first marked improvements in artificial kiln seasoning. Experiments and research in this direction were taken up at the Institute in the early years after the War, and this small leaflet gives briefly some of the results which have been reached —results which are at least as important economically as in temperate zones. The general principles of the steam-heated internal-fan kiln and four types of furnace kilns are discussed, the direct-heated forced-circulation furnace kiln, the indirect-heated internal-fan furnace kiln, the new F.R.I. furnace kiln and the hot air kiln. The results of tests show that a steam-heated internal-fan kiln is suitable for the seasoning of almost all kinds of woods. Of the furnace kilns, the first mentioned above is suitable for drying furniture woods, the second for drying packing-case timbers only, the third for the slow seasoning of furniture woods and the fourth for completing the drying of partially air-seasoned half-wroughts for the manufacture of certain types of articles. The third of these furnace kilns is cheaply manufactured, was designed at the Research Institute and is termed the indirect-heated thermal-circulation furnace kiln.

The fourth furnace kiln, the hot air kiln, briefly alluded to here, is discussed in detail in Leaflet No. 5, issued by the Research Institute in 1941. It is common knowledge that air-seasoning of timber is slow but yields eminently satisfactory results, well known to previous generations. In these hurrying days of greater demand, assisted by two major wars, the periods required to produce air-seasoned material of the various species of timbers are too long. As an example, 1-inch planks of hardwoods suitable for furniture manufacture take at least three to four months to become properly air-seasoned, and larger-sized timber correspondingly longer. The kiln considerably reduces the period. For example, it is estimated that 2½ in. × 2½ in.-blanks of refractory hardwoods cut from planks which have been air-seasoned for about two months can be completely seasoned in about fifteen days in a hot air kiln of this type. This kiln is a masonry chamber provided with a number of ducts in the floor through which hot gases from a wood-burning furnace are passed. The chamber is fitted with racks for holding the half-wroughts of wood to be seasoned. These consist of shuttles, bobbins, picker arms, helves and tool handles.

FORTHCOMING EVENTS

(Meeting marked with an asterisk is open to the public)

Friday and Saturday, July 24-25

BRITISH ASSOCIATION (DIVISION FOR THE SOCIAL AND INTERNATIONAL RELATIONS OF SCIENCE) (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 10 a.m.—Conference on "Mineral Resources and the Atlantic Charter", to be opened by Sir Richard Gregory, Bart., F.R.S.*

Friday Morning Session

Chairman: Sir Thomas Holland, K.C.S.I., F.R.S.; Speakers: Prof. H. H. Read, F.R.S., Prof. P. G. H. Boswell, F.R.S., and Prof. C. B. Fawcett.

Friday Afternoon Session

Chairman: Sir William Larke; Speakers: Prof. W. R. Jones, Sir Lewis Fermor, F.R.S., Lt.-Col. the Hon. Colin A. Campbell.

Saturday Morning Session

Chairman: Dr. C. H. Desch, F.R.S.; Speakers: Dr. E. F. Armstrong, F.R.S., Dr. W. H. Hatfield, F.R.S., Dr. David Williams, and Sir Harold Hartley, F.R.S.

Saturday Afternoon Session

Chairman: Sir Stafford Cripps, P.C.; Speakers: Prof. J. G. Smith, Dr. W. A. Lewis, Dr. E. P. Penrose, Mr. A. Notman, Dr. O. W. Roskill, and Dr. L. Dudley Stamp.

Tickets from the Secretary, British Association, Burlington House, Piccadilly, London, W.1.

Saturday and Sunday, August 1-2

ASSOCIATION OF SCIENTIFIC WORKERS (IN COLLABORATION WITH T FEDERATION OF AYRSHIRE SCIENTIFIC FILM SOCIETIES) (at Ayr). Conference on "The Scientific Film and Scientific Film Societies".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on before the dates mentioned:

VETERINARY INVESTIGATION OFFICER—The Secretary, West Scotland Agricultural College, 6 Blythswood Square, Glasgow (July 3

LECTURER in MATHEMATICS in the Technical College, Cardiff—T Director of Education, City Hall, Cardiff (July 31).

GRADUATE IN ENGINEERING TO TEACH TECHNICAL SUBJECTS A ALSO TO ACT AS ORGANIZER OF THE TECHNICAL CLASSES in the Basin stoke Queen Mary's School and Technical Evening School—T County Education Officer, The Castle, Winchester (endorsed 'Basin stoke') (July 31).

TWO DEMONSTRATORS (MALE OR FEMALE) IN ANATOMY—The Regi trar, The University, Sheffield (July 31).

LECTURER IN THE DEPARTMENT OF CHEMISTRY—The Registr University College, Southampton (August 4).

LECTURER IN MECHANICAL ENGINEERING in the Cannock Cha Mining College—The Director of Education, County Educati Offices, Stafford (August 7).

HEAD OF THE ENGINEERING DEPARTMENT at the County Technic College, Wednesbury, and COUNTY LECTURER IN ENGINEERING f South Staffordshire—The Director of Education, County Educati Offices, Stafford (August 7).

LECTURER FOR EVENING CLASSES IN CHEMISTRY—The Princip Technical College, Kingston-upon-Thames, Surrey.

GRADUATE IN ENGINEERING, and a GRADUATE FOR GENER SCIENCE AND MATHEMATICS, at the Eastbourne Technical School—T Education Officer, Education Offices, Eastbourne.

CHEMIST OR CHEMICAL ENGINEER WITH EXPERIENCE OF RUNNIN AMMONIA SODA PLANTS and with knowledge of the heavy chemic industry, for India—The Secretary, Overseas Manpower Committ (Reference 338), Ministry of Labour and National Service, Hanwa House, Red Lion Square, London, W.C.1.

TWO DEMONSTRATORS IN PHYSIOLOGY—The Professor of Physiolog The University, Liverpool.

SOCIAL MEDICINE

THE announcement that the Nuffield Provincial Hospitals Trust is prepared to endow for ten years the creation of a professorship of social medicine in the University of Oxford has created various favourable comments in the general Press. It is one of the signs of the times, which all indicate that the social aspect of medicine is coming inevitably to the fore as the public realization and appreciation of its importance increases.

The War has expedited the change in public opinion indicated by the proposal, but the course of things has been long proceeding. The Elizabethan conformation of the Poor Law meant that no one need starve or lack medical aid in England. It took long centuries to realize the extent of the obligation this imposed, and only recently has its full value been appreciated, behind which is the philosophy of social consciousness which has become more and more sensitive as the decades have succeeded one another. Gradually, voluntary and official hospital provision has grown, including that of special hospitals for particular complaints, and the habit has been created—indeed it is a necessity—of hospital treatment of major diseases. Not only this, the growth of 'specialism' and consequent extension of medical work implied has necessitated special provision, and few people can now deny that they are better treated in these hospitals than in private practice.

The trend is always increasing, and this must of necessity go on, because the standard of effort advancing medical science is always improving. It is to meet this increasing standard of medical attendance that the Nuffield professorship in social medicine now created is especially directed ; it will also have an indirect value in preventing disease, or what in many instances is tantamount to that, in treating it before it reaches an incurable stage. There is by no means enough liaison between the general medical practice of to-day and preventive medicine. Such universal problems as motherhood, childhood and youth, tuberculosis, cancer, venereal diseases should not be left to medical individuals or groups of individuals. Much has been and is being done by various groups (often in collaboration with the Ministry of Health) ; but it is not enough, because only a minor percentage of the population is reached by such methods. Whether the State should take over responsibility is a moot point ; for the grave risk of compulsion is here implied. Compulsory inoculation or treatment for various types of disease might, on casual consideration, seem the easiest way out ; but various inquiries concerning its effects in countries where it exists show that disturbing consequences often arise. In a democracy such as ours, enlightenment and education, especially in healthy living and in medicine as a social science, are clearly the best solutions to a problem of ever-increasing complexity.

This process, which has been increasing in emphasis decade by decade, has been expedited by the War, and many medical practitioners now in military service are unwilling to go back to the hampered conditions of ordinary single-man medical work. Medicine is clearly developing as a social science and team work is increasing, thus casting off its fetters as a closed profession. As Sir Arthur Newsholme has pointed out*, "in future practice, blundering experiment and erroneous procedures can best be avoided when one knows what others have done and what has been the outcome of their practice".

The procedure of medical insurance is evidence of this process. Already a third of the working-classes, including many black-coated workers, are within the national scheme ; and there is concurrence of evidence from the British Medical Association, representing the great mass of the practitioners in Great Britain, of testimony to the fact that this process should be extended to the dependants of insured persons. This would mean that four fifths of the population of the country would be removed from the evils of cash nexus which at present fetters medical work. It is not difficult to see the future course of events. Ere long, under the pressure of the medical profession, all workers will have to be provided for by a national system of medical service. Whether the expenditure incurred will come solely out of rates and taxes, or whether a system of payment by weekly stamps in which all have partnership—employers as well as employed—and in which the State sees that equitable provision is made, is still disputable ; but there can be no doubt as to the trend of events in this connexion. Everyone is interested in the maintenance of health ; family health and industrial health are merely aspects of the same problem, and everyone is concerned at the present lack of continuity in such medical assistance as is forthcoming. The financial aspects alone of this discontinuity are serious. While not advocating any undue increase in consultant, pathological and X-ray aids to medical practice, their lack is often felt deeply by the general practitioner to the detriment of the patient. In particular, the fastidious general practitioner often leaves off attending his patient when in more favourable circumstances he would like to continue to watch him. This consequence of discontinuous medical care is to the detriment of both medical man and patient.

For this state of things the growth of medical science is largely responsible. It is no one's fault, but the present condition of things is becoming intolerable, and there is an increasing call for the availability of expert medical help to the full extent needed.

It has been increasingly clear that there is need for a closer unification of local and national medical services, and few will doubt that such unification should not be left to medical men, but should be organized by the public authorities in consultation with the former. This will be one of the urgent immediate problems in medicine viewed as a social science.

The Nuffield Trust endowment for this and other purposes will facilitate matters. One may rightly wish God-speed to its efforts, and special success to the new professor of social medicine.

SCIENCE AND RELIGION

The Human Meaning of Science

By Arthur H. Compton. (John Calvin McNair Lectures.) Pp. xiv+88. (Chapel Hill, N.C.: University of North Carolina Press ; London : Oxford University Press, 1940.) 6*s*.

THIS is a small book on a very large subject, and it would be unreasonable to expect any comprehensive or fundamental discussion in three lectures. What the author gives us is interesting enough, though the reader must often find himself asking questions which in these pages at least have no answer. The second lecture, which is on the subject of human freedom and physical law, is a lucid and valuable statement of an argument for freedom. Dr. Compton does not allege that modern developments of physics can be used as an argument to establish the reality of freedom, but he does hold, and surely with good ground, that the argument in favour of determinism which was based on the alleged universality of natural law no longer possesses its ancient cogency. The newer quantum mechanics are "consistent with the postulate of freedom". There is no discussion of the meaning of freedom, but it appears to be identified with the "effectiveness of purpose" as in the following sentence: "My experience of the effectiveness of purpose is more direct and cogent than any logical argument based upon scientific generalizations".

The first lecture in the book is on "Science, Religion and Human Growth", and it must be confessed that to one reader at least it has seemed to err on the side of optimism. We are taken rapidly through the obvious advantages which science has conferred on the human race, and stress is laid on the mental and spiritual gifts of science. We have been taught "the importance of reliable knowledge". We have "gained confidence in our strength" and have therefore a more hopeful outlook on the future than our unscientific ancestors. One cannot help wondering whether these statements are accurate. It may be that we understand the importance of reliable knowledge, but the fact is that there never was a period when men were more easily swayed by propaganda, which is usually the dissemination of unreliable knowledge, nor does a contemplation of the possibilities of scientific warfare conduce in all minds to a hopeful view of the prospects for civilization.

There is, however, one consequence of scientific civilization as defined by Dr. Compton about which his language is ambiguous. "It would seem to be a corollory of the growing complexity of civilization that people must give more and more attention to the rights of others." The word "must" is notoriously misleading, and it is not clear whether the author means that science and technology produce altruism or whether the progress of science and technology ought to be accompanied by a growth of conscience. On the whole, Dr. Compton seems to believe that law and justice not only ought to prevail but necessarily will prevail. We may at least agree that unless co-operation is achieved and placed upon firm foundations, the conditions that make advance in science possible will eventually disappear. No doubt this would be most deplorable, but it is not evident that it could not happen.

The third lecture, on "The Need for God in an Age of Science", would require a long discussion to do justice to its argument. The thesis is that "the hypothesis of an intelligent God gives a more reasonable interpretation of the world than any other", and the chief emphasis is laid upon the evidence of "direction" or of intelligence in evolution. "Evolution is in itself no explanation of these remarkable processes; the theory of evolution is merely the description of how the processes occur. It is, however, difficult to avoid an interpretation which sees underlying these evolutionary processes an intelligent power, directing them with some great purpose." I have, naturally, no quarrel with this conclusion, but I am moved once again by reading this stimulating little book to wish that I knew precisely what was meant by the "theory of evolution".

W. R. MATTHEWS.

THE OLD AND THE NEW IN INDIA

Ethical Ideals in India To-day

Conway Memorial Lecture delivered at Conway Hall, Red Lion Square, W.C.1, on March 22, 1942. By Dr. Edward Thompson. Pp. vi+39. (London: Watts and Co., Ltd., 1942.) Cloth, 2*s.* net; paper, 1*s.* net.

THERE is a certain appropriateness in contemplating the development of ethical ideas in contemporary India; for there are few countries, Russia and China excluded, where the march of history has engendered such violent conflicts in the mental and moral attitudes of peoples as in Hindustan. Dr. Edward Thompson, who has devoted many years of service to India, did well, therefore, in choosing this theme for his Conway Memorial lecture this year.

The main thing about recent ethical ideas in India, which emerges from Dr. Thompson's exposition, is that they are much more intimately allied to the modern political movement than ethical ideas have been in Europe. So that they would seem, at first sight, to be in the main tradition of Indian thought, which looks at man as a whole, and in which man's philosophical, ethical, æsthetic and political ideas have been regarded as all part and parcel of each other. Yet, these contemporary ethical ideas in India, being more intimately associated with the individual great men of whom Dr. Thompson speaks in his lecture than with schools of thought and religion, partake of the character of the modern European, individualist sense of values.

This peculiarity is implicit in the workings of India's recent history. The feudal structure of society broke down in India in the last hundred years. The old self-governing, self-sufficient village system was smashed and the locomotive connected the most obscure corners of the land to the town, the seaport and the world market. "Telegrams and anger" came into India and the "steel frame" of a central government introduced a political and economic system which changed the very fabric of old social relations. The capricious and fluctuating prices of grain in the exchanges of the world destroyed the uncanny, unknown 'fate', symbolized in the all-powerful Nature, and substituted a new unseen fate, the stockbroker. All the ancient cultural traditions, though surviving as quasi-feudal forms in the very midst of this modernity, began to corrode from within.

In such an India, in the midst of these anachronisms, the difficulties of regeneration having been increased by the frustrations of political advance, the very best minds of India struggled to adapt themselves and their country to the outside world, which itself was changing fast. The shocks upon their sensibilities were acute and so were their reactions.

From Ram Mohan Roy, the first great modern Indian who believed in the truth of the unity of all mankind, to Jawaharlal Nehru, a believer in international socialism, there have been many vital and original responses to the complex questions of our age. Dr. Thompson chooses for special attention the answers of three significant men: Gandhi, Tagore and Iqbal. All three, ranking high among world thinkers, are shown to be oscillating between the old and the new in contemporary India, torn almost like that great Englishman whom Shakespeare pictured as the Prince of Denmark.

What exactly was the problem they posed before themselves, and how did they seek to solve it? I have already referred to the great social upheaval, the overturning that happened in India after the coming of the British. That was the atmosphere in which these three men grew up, and, inevitably, they asked themselves to what extent they could actively help or hinder this overturning, and what was the ethics of behaviour called forth from them.

Gandhi read Ruskin's "Unto This Last". Perhaps he also heard "the shrill cry that goes up from the factory chimneys, fiercer than the furnace blasts". Anyhow, he determined to change his life in the light of that book, or rather in the light of the three principles he deduced from it: (1) the good of the individual is contained in the good of all; (2) the dignity of labour; (3) the life of the tiller of the soil and handicraftsman is to be preferred to all. After serving in an ambulance unit in the Boer War, he added to this the belief in *Brahmcharya*, or sexual continence. Further, since he had become aware of the restrictions placed on Indians by the South African Government, he elaborated a further doctrine called *Satyagraha*, or soul-force, with which he sought to struggle against authority, the actual method being the old Indian practice of *Dharna*, the aggrieved sitting at the doorstep of the oppresser until his grievances were remedied. This 'stay-put' strike, backed by soul-force or truth-force, later known as civil disobedience, was to be characterized by a strict *ahimsa*, which Gandhi translated as non-violence, and which has become familiar in our time through its adoption in the mass campaigns of the Indian National Congress in its struggle for freedom.

Dr. Thompson's exposition of Tagore's ethical beliefs is also an implied criticism of Gandhi's doctrine. For Tagore, though aware of the enormous gains achieved by non-violence, considered it to be ethically an inadequate doctrine. "I believe," he wrote in an open letter to Gandhi, "in the efficacy of *ahimsa* as the means of overcoming the congregated might of physical force on which the political power in all countries mainly rests. But like every other moral principle, *ahimsa* has to spring from the depth of mind, and it must not be forced upon man from some outside appeal of urgent need. . . . When it concerns an immense multitude of men of different traditions and stages of culture, and when the object for which such repression is exercised needs a prolonged period of struggle, complex in character, I cannot think it possible of attainment."

Tagore himself, "choked for breath in the hideous nightmare of our present time", tried to be an individual and to teach others to be individuals in his school at Shantiniketan. He regarded with contempt the 'mendicancy' of Gandhi's method and held the more positive belief that "weakness is sinful, because it is a menace to the strong and the surest cause of downfall for others than those who own it." This individualism, which owed a great deal to the West, alternated with many, even anthropomorphic, moods in him before it reached a kind of scientific humanism towards the end of his life. Then Tagore was inclined to believe in a new morality of the poor such as may arise from a change in the *status quo*, as a reaction against the prevalent morality in which the rich can steal millions but the poor are imprisoned for stealing a loaf of bread, a morality which, he believed, was extraneous to society and had lost touch with it.

The approach of the North Indian poet, Muhammad Iqbal, shares the positive urge of Tagore, though, being more concerned to re-interpret Islamic thought in order to supply the lacunæ in the theoretical background of modern Muhammadan communities, he found himself adopting the old ethics of the Koran. Nothing less would do than the formation of a holy kingdom, *Pakistan*, somewhere in the north of India, where the old brotherhood of Islam would be revived. This brotherhood would not be liberal, nor based on the recognition of human or ethical equality of men, but on the strong individual re-orientating, or rather stretching, the old gospel to admit of modern scientific ideas such as evolution, God as time, the final judgment day as an alternation of day and night when good deeds bring their own reward, as in the Hindu doctrine of *Karma*.

Except for Tagore and Nehru, both imbued with the atmosphere of our age and straining for a new morality, the great leaders of Indian thought fail in the final analysis and yield to the past. Rising on the crest of an emancipatory movement, the children of a great overturning in Indian history, they resent further change. The resistance to the machine in Gandhi's ethics is reminiscent not only of Ruskin but also of the illustrious Tolstoy, the man who greeted the abolition of serfdom only to cry halt in front of the English industrial revolution.

Why does this peaceful Yasanya Polyana ethic reappear in more or less the same form at the ashrams of Sabramati and Wardha ? Dr. Thompson has a brilliant flash of insight into such recurrences when he compares Gandhi's recommendation of non-violence to the Abyssinians against Mussolini, with Chamberlain's appeasement of Hitler. In fact, the whole lecture shows an uncannily sympathetic grasp of the Indian attitudes in their interconnexion with world modes of thought. I have not the space to bring out the significance of all the attitudes Dr. Thompson treats of, but I may answer the question I have just raised.

It is possible that non-violence springs from a feeling of weakness in the face of the tiger; it is conceivable that it owes a great deal to the lack of cohesion in the forces behind one; but it is certain that it springs from an almost unconscious acquiescence to those who seek to preserve the past, even in putrescent decay, and who dread another over turning. Because non-violence in India implies active moral resistance, it is certainly more positive than appeasement, but any dynamism it has is due to its organized application in mass campaigns rather than to the individual who conceived it, however high the ethical merit of the conception—the proof of the pudding, like that of any other, is in the eating. We shall see how non-violence fares in its application against the marauding hordes of Nippon now ranged on India's frontiers, if the Government still ties India's hands and if Gandhi still insists on applying it. MULK RAJ ANAND.

PAST, PRESENT AND FUTURE OF AVIATION

Air Power and Civilization

By M. J. Bernard Davy. Pp. viii+202+8 plates. (London: George Allen and Unwin, Ltd., 1941.) 8*s*. 6*d*. net.

MR. DAVY'S book merits the attention of many people, for it is comprehensive. Those who are interested in the days previous to the invention of flight will find some very interesting chapters going back to the ideas of Leonardo da Vinci and tracing the subject through the great balloons of Montgolfier to the advent of the aeroplane. Then Mr. Davy deals with the historical production of flight, and here nobody has greater authority. I myself am very critical of the contributions by different people which have been very much mixed up lately with fallacious claims. Mr. Davy, with his knowledge and study of these early times, brought about no doubt by his association with the aeronautical exhibit in the Science Museum, gets everything right, so that I look upon his early historical side as something well worth preserving and referring to, should reference back be sought on any point.

The book then passes to the power of the aeroplane, describing with great interest the first aerial attack and the use of the aeroplane as a lethal weapon, culminating in the present situation, and then it deals with the future. It will be seen, therefore, that there is little in aviation, approached in a general way, that Mr. Davy does not deal with; and for that reason his book must command the respect and attention of all students of this great problem.

Mr. Davy does not think that internationalization of air is the complete solution, or that it could be feasible. I cannot agree entirely with this. I think so much depends on at what time it is done. It could be done now, but if it is put off until it is too late it will never be done, and the continuance of subsidized air lines as cover for air forces will start again. Mr. Davy thinks that regional air police forces might be a beginning, eventually coming all together in a world federation. It is a matter of how much we can do. No one will dispute that a world federation of the air is imperative. Whether it can be done all at one time, or whether the idea of regional air police forces does not lend itself to further conflict, is for the reader to decide. But here is an attempt to deal with this great question of air control after the War, and the more people are conversant with the ideals and the difficulties the sooner we may reach some solution of this difficult problem.

Mr. Davy does not direct attention to what, I think, is rather a curious situation in flight. There are many things we use to-day which were not possible for man to have created—say two or three hundred years ago—because the technique in manufacture was not available to him. For example, the motor-car could never have been built for the Romans; they had neither lathes, the metallurgical knowledge, nor the engineering ability. But look to-day at a modern high-efficiency glider—a glider with a rate of fall of 1 in 20; there is nothing in it that could not have been built a thousand years ago with ease. So that although actual power flight waited on the internal combustion engine, had gliding been indulged in seriously and the basic principles of gliding flight appreciated, we could indeed, a thousand years ago and more, have had controlled gliding flight with its very vast potentialities already available to mankind before the advent of a power unit. In fact, I think, gliding flight is one of those things which came very much later in history than was possible.

Mr. Davy says that Nature did not provide any devised pattern for man to copy, but I think for gliding flight with those very high aspect ratio birds such as the gull, there was indeed a pattern to be copied, and although propulsion by the flap wing introduced very grave mechanical difficulties, yet the gull is so lazy and uses air currents with such efficiency that it did not require very great intelligence to realize that the trouble could have partially been got over by using rising currents of air apart from propulsion. Even to-day we have a lot to learn from Nature, especially in noticing that maximum power in the bird is used not only for getting off, but in landing, whereas all our aeroplanes land on the straight dead glide—a system which is not utilized in Nature except occasionally on the water. Usually tremendous power is exerted to stop forward movement and give lift just before contact with the ground. Something along these lines is badly wanted to-day, as all aircraft are in the greatest danger when landing.

Due tribute is paid to Caley, Henson and Stringfellow, which they well deserve. Stringfellow, I see, gave performances of a model in Cremorne Gardens in 1848. This remarkable seat of aviation and entertainment, now filled by Lot's Road power station, must have been a very attractive rendezvous. Some of the first ascents by balloon were made from these Gardens.

The work of Pilcher has not been given enough attention in the book. He was not only a follower of Lilienthal in gliding, but he himself also invented some very remarkable devices. For example, he was towed up into the air as a kite by a system of tackle, gearing himself up and being pulled by a horse. Along these lines he did exactly what is to-day done by a motor-car pulling a glider up as a kite to start with before it glides. Lilienthal never did that, always relying on downward flight in a rising column of air on the surface of a hill.

I do not think the Wrights' patent is put in the clearest way. This patent was the claim that the warping of the wing or the aileron did not restore lateral stability and that if you wished to restore it, it was not only necessary to put the extra angle on the wing, but it was also necessary to interconnect this with rudder action of a reverse type. Otherwise the extra drag due to the increased angle of the wing rendered nugatory the potential extra lifting power. Mr. Davy deals with the Wright-Langley dispute in a very interesting part of his book. It was a situation which is little appreciated in Great Britain.

In the early heroic epoch of flight in Europe, not enough tribute is paid to the first Gnome engine, which was a revolutionary design. It was self-cooling by the rotation of the cylinders, and for its day was extremely reliable. Another interesting point is that due to the exhaust valve in the top of the cylinder, the engine consumed more lubricating oil than petrol, and it was not until somebody remembered the extraordinary properties of castor oil, which becomes stickier the hotter it gets, that this engine became a practical proposition. This engine did more to help along European aviation than any other factor.

I have told the story before of how on behalf of the Aero Club I went on a deputation to the War Office offering to lend two machines for the manœuvres and was rebuffed by them saying that they did not see any uses for aircraft in war. I always consider this a very remarkable episode in my life, but Davy quotes an equally remarkable incident, which is that "in 1907 the Wright brothers corresponded with the First Lord of the Admiralty concerning their invention, and they were informed by him that, after consulting expert advisers, the Board of Admiralty 'were of opinion that they [aeroplanes] would not be of any practical use to the Naval Service' ". It sounds amusing now, but the suspicion rather creeps into one's mind as to whether the same thing is not being done to-day relative to new inventions.

I am glad the bombing of Rotterdam on May 14, 1940, is brought into the book, because here I think is one of the most dastardly air attacks that was ever made or ever will be made. Fifty thousand casualties, including thirty thousand dead, against the unoffending Dutch is a blot upon the *Luftwaffe* that can never be extinguished.

I am pleased to find that Mr. Davy accentuates the point that real progress on beneficial lines will not really occur if the design and manufacture of aeroplanes is to be determined by the requirements of naval and military air forces. That has been one of the reasons more than any other that progress has not been made along real civilizing lines. There is much to be done—assisted take-off, high wing loading, non-inflammable fuel, better landings, pressurized cabins, jet propulsion; these are all problems of the future which will be great contributions towards flying as a safe and prosperous form of transportation.

Mr. Davy deserves great credit for his book. Not only will the reading of it convey immense knowledge of a subject which from the practical point of view is only some thirty years old, but also it must leave in the minds of all readers food for contemplation and thought as to the future. If I have any criticism, it is that the illustrations might have been better selected, but I am glad to see included the historical picture of the first flight on December 17, 1903.

BRABAZON OF TARA.

LEUKÆMIA IN ANIMALS

Spontaneous and Experimental Leukæmia in Animals

By Dr. Julius Engelbreth-Holm. Pp. xxiii+245+24 plates. (Edinburgh and London: Oliver and Boyd, 1942.) 15*s*. net.

LEUKÆMIA, though a relatively rare disease, has many appeals. The clinician is confronted with a progressive and mysterious increase in the white cells of the blood and blood-forming tissues, resulting, unhappily, in the loss of young life. For the hæmatologist, the chief problem is the origin of these blood cells; the specialist in cancer research is concerned since there are many features in common between leukæmia and malignant tumours. The student of comparative disease, the virus investigator and the geneticist find fascinating problems, while the theoretical pathologist may well regard leukæmia as a substantial prop to the theory of cellular pathology which was clearly enunciated by Rudolph Virchow (1858), himself one of the foremost investigators of human leukæmia.

Leukæmic conditions are found with some frequency in birds and mammals. Fowl leukæmia is most often a disease of the lymphocytes, whether they are circulating in the blood stream or confined to certain regions such as the lymph glands, spleen or bone marrow. There is a close resemblance between these lymphogenous leukæmias and the economically important 'fowl paralysis' (neuro-lymphomatosis). Curious seasonal variations are seen with fowl leukæmia, reminiscent of the seasonal variations in rate of growth, fatality and transmissibility of certain fowl tumours (sarcomata) induced by carcinogenic agents (Peacock, 1935).

Spontaneous leukæmia is also found in adult dogs, pigs, cattle and rodents. In the mouse it is a common disease occurring in forms very like those known in human beings, so that mouse leukæmias have been intensively studied. Various kinds of white blood cells are affected and enormous numbers of such newly formed cells appear in the blood, while the organs in which these cells are normally congregated (lymph glands, spleen, bone marrow and to a lesser extent the liver) may be greatly enlarged from massive deposits of abnormal cells. On the whole, birds and mammals show an absolute preponderance of leukæmias in which the lymphocyte is the chief cell affected.

Among the many varieties of fowl leukæmia are some which can be transmitted to healthy birds by cell-free centrifugates and filtrates (Ellermann and Bang, 1908). Transmission succeeds with remarkably small doses. Furth (1932) found that as little as 0·000001 c.c.m. fowl plasma could transmit the disease. Chickens a few days old are more susceptible than adult fowls, and seasonal variations in 'takes' are known. A filterable virus is naturally enough thought of as the cause. There is evidence that the virus of fowl leukæmia is not strictly species specific, for it can be transmitted to guinea fowls, pheasants and turkeys. When introduced into the blood of susceptible birds, the virus disappears from the blood vessels for a time, localizing in the bone-marrow and possibly spleen and liver, where it induces proliferation of blood cells. The virus is about 65–75 mμ in size, is thermo-labile, survives prolonged drying, is destroyed by oxygenation, but resists irradiation. It can be cultivated *in vitro* only in the presence of cells. Thus it has many resemblances to the causative virus of the Rous sarcoma of fowls. There is evidence of natural immunity in some birds and active immunization has succeeded.

Transmission of leukæmia is also possible in rodents. In non-inbred strains of mice, transmission succeeds in animals of similar genetic constitution. In mixed strains, transmission fails unless resistance is lowered by X-ray exposure. Inbred strains can be produced with a high incidence of spontaneous leukæmia. The disease can be transmitted only by means of living cells, no cell-free virus having been demonstrated. A single cell injected intravenously may suffice to transmit the disease (Furth and Kahn, 1937). Dispersion and multiplication of such cells, apparently without co-operation of the host's tissues, is responsible for the disease. There is, however, some evidence that metabolic changes, somewhat like those seen in malignancy, occur in lymph glands of leukæmic strains before morphological signs of leukæmia can be recognized (Victor and Potter, 1935), but much more work is required on this obscure subject.

The importance of heredity in spontaneous animal leukæmias has been extensively studied, especially in mice. It would appear that there is a maternal, non-chromosomal factor which differs from the milk-transmitted factor demonstrated by Bittner (1939) in the case of cancer of the breast in some mouse strains. Hereditary factors play an important part in susceptibility to transmitted leukæmia, but the genetic constitution of the tissue inoculated complicates the experiment. Mice of an inbred strain susceptible to inoculation with tissue from one line may thus be resistant to leukæmic tissue from another line.

It has been claimed at various times that experimental leukæmia can be produced by the action of carcinogenic substances, just as sarcomata are produced by these. Striking blood changes do occur in such circumstances, but they are not wholly convincing of leukæmia and are seldom accompanied by blood-cell infiltration of the tissues. Investigators have preferred to speak of them as leukæmoid changes, reserving for the future the right to change their views as to the true nature of such conditions. In mice of known genetic constitution showing a very low incidence of spontaneous leukæmia the condition can be produced by carcinogenic agents. Thus in the Aka strain in which 50–70 per cent of animals more than eight months old develop lymphogenous leukæmia, carcinogens induce sarcoma and carcinoma as well as leukæmia in mice less than five months old (Engelbreth-Holm, 1940). Such treatment seems to accelerate both tumour and leukæmia production. The incidence of leukæmia can also be increased in mixed stocks and purer strains by irradiation with X-rays or by œstrogens.

It is not surprising, therefore, that many investigators now accept Ribbert's (1904) view that leukæmias in animals are neoplastic in nature, but whether they are truly malignant or benign is not certain. There is no clear-cut border-line, however, between lymphogenous leukæmia and lymphosarcoma in mice. Leukæmic disease, as with new growths, commences as a local change and becomes generalized, any differences being explained as consequences of the special relationship of leukæmias to the vascular system. Since there are so many clinical and pathological analogies between the animal and human leukæmias it is obvious that investigations into their relationship to viruses, transmissibility and genetic constitution hold out a good deal of promise for the future, and man may once again be indebted to his humbler relatives for the solution of a baffling problem.

Dr. Engelbreth-Holm, director of the Cancer Research Laboratory of the Danish Anti-Cancer League and himself an original worker on animal leukæmias, is to be congratulated on a fascinating book written at the invitation of the Scientific Advisory Committee of the Lady Tata Memorial Trust. Not only research workers in this very specialized field of blood diseases but also all who have an interest in the progress of experimental medicine will enjoy the clear presentation of a variety of facts drawn from a widely dispersed literature. Special commendation is due to the translator of the Danish manuscript, the editors of the English version and the librarian of the National Institute for Medical Research, London, who checked the references, for their labours.

G. R. CAMERON.

CONDITIONED REFLEXES

Lectures on Conditioned Reflexes

Vol. 2: Conditioned Reflexes and Psychiatry. By Prof. Ivan Petrovitch Pavlov. Translated and edited by Dr. W. Horsley Gantt. Pp. 199+7 plates. (London: Lawrence and Wishart, Ltd., 1941.) 8*s*. 6*d*. net.

ONE is often grateful for the existence of general surveys which are written for international congresses or commemorative volumes. They provide excellent opportunities of summarizing a subject in a form which gracefully supplies entertainment and instruction. It is very doubtful, however, if there is any justification for the collection and republication of the general reviews written by a single author. Inevitably they cover large areas of the subject, and inevitably they overlap. Brief accounts of the same illustrative experiment reappear time after time, until one longs for tables of data and experimental protocols. Of the fifteen chapters in this volume, eleven consist of general articles. The translator has carried out extensive condensation and excision, but far too much that is redundant remains.

The last chapter is by far the best. It was written in 1935, the year before Pavlov's death, and in it he has summarized in twenty pages the whole of his work on conditioned reflexes. It is the most complete and orderly presentation in the book. The other outstanding chapter appeared in the *Psychological Review* in 1932, translated by Dr. R. S. Lyman. Its style is clear and vigorous, and the subject-matter is scientific polemic at its best. Pavlov defends himself against Guthrie and Lashley by a masterly restatement of his own position, and his criticism of Lashley is fair and penetrating. His comments on experiments on maze-running exemplify his approach to a problem and his instinct for profitable analysis.

The remainder of the book is disappointing. The translation is obscure and clumsy, and there are no references. The introduction contains a biographical sketch of Pavlov's later years, and a section entitled "A Critical Evaluation of Pavlov's Work". This consists of a hotchpotch of the considered and unconsidered opinions of physiologists and psychologists, and a remark addressed to the author by Bernard Shaw at Lady Astor's.

Since 1927, Pavlov and his school seem to have turned their attention chiefly to the study of the disturbances of behaviour, which he calls experimental neuroses. The methods used include the application of very strong stimuli, the protracted use of inhibitory stimuli, the presentation of positive and inhibitory stimuli in quick succession, and castration. On the basis of their behaviour in these conditions, Pavlov divides his dogs into choleric, sanguine, phlegmatic and melancholic types. This classification depends on incompletely defined concepts of 'strong' and 'weak' nervous systems, but it is claimed that it is of use in the production of neuroses at will, and in their cure by appropriate treatment.

When he was more than seventy, Pavlov plunged into the study of human psychiatry. He began to attend psychiatric clinics, and re-opened the writings of the clinical psychiatrists. Naturally, he began to interpret these new phenomena in more familiar terms. In these lectures, analogies abound between human neurasthenia and experimental neuroses, between schizophrenia and chronic hypnosis in dogs. Paranoia and obsessional neuroses are said to be manifestations of pathological inertia of points of the cortex. The classification of men into artists and thinkers, and the conception of words as conditioned stimuli of a second order are further examples of Pavlov's passion for simple hypotheses with which to try to reduce chaos to order.

It is a pity that Pavlov did not begin by trying to verify in man his conclusions from animal experiment. Instead, he writes as one bringing light to the blind. In 1927, he began the last chapter of "Conditioned Reflexes" with a firm warning against the premature application of "these first steps in elucidating the physiology of the cortex . . . to the intricate problems of the higher psychic activities in man, when at the present stage of our work, no detailed application of its results to man is yet permissible". It is difficult to feel that the subsequent experimental work described here has provided the evangel that alone could justify Pavlov's disregard of his own warning. He even supplies evidence himself that his results on the dog are not, in fact, generally applicable. Speaking of the spread of prolonged inhibition over the hemispheres in a dog, he remarks that "this has been shown from the experiments by Voskresensky on monkeys, to be a special property of the dog's nervous system". In spite of this, we find that this spread of inhibition over the cortex is invoked to explain sleep, hypnosis, and the states of hebephrenia and catatonia in man.

The main difficulty in Pavlov's work, the extreme complexity of conditions from which the stimulus had to be isolated, was brilliantly overcome. The second major difficulty, the degree to which experimental conditions interfered with normal cortical function, he at least recognized: "Hypnotization begins when the dog enters the experimental room, sometimes even before he gets on the stand, increasing as the experiment progresses". The insuperable difficulty was that Pavlov was limited to external observation of stimulus and response. He could trace roughly the anatomical pathways involved, but could know nothing of the intermediate processes. Studies on the whole animal must always be interpreted in the light of analytical experiments, and in the absence of such knowledge it is not surprising that Pavlov has bridged the gap between stimulus and response by a mass of hypotheses. Sometimes, by varying his conditions, he has been able to weed out false hypotheses, but often they are left to buttress one another. Attempts by others to re-interpret his data have not been more successful. Denny Brown's substitution of 'attention' and 'distraction' for Pavlov's 'irradiation' and 'waves of inhibition' seems to depend on personal preference, and the great advances in our knowledge of the behaviour of the spinal cord in the last ten years have made interpretations based on classical cord physiology look a little premature.

With the development of a real physiology of the cortex by Adrian, Bremer and Dusser de Barenne, a surer basis for interpretation is being built up. It is already possible to put some of Pavlov's broader hypotheses to experimental test by electrical methods in the intact animal. Studies of cerebral activity in animals will for long be based on Pavlov's work, and the English-speaking worker will turn first to Anrep's translation of "Conditioned Reflexes". If the present volume induces new students of cortical physiology to turn back to that great work, it will have been of lasting value.

D. WHITTERIDGE.

SEPARATION OF ISOTOPES AND THERMAL DIFFUSION*

By PROF. JAMES KENDALL, F.R.S.
University of Edinburgh

THE fact that the same element may exist in two or more forms, which are chemically identical even though their atomic weights differ, was first noted by Soddy (1910) in connexion with radioactive elements. A little later Sir J. J. Thomson (1913) showed, by the method of positive ray analysis, that neon, with an average atomic weight of 20·2, is a mixture of two kinds of atoms with masses 20 and 22 respectively. The brilliant extension of this method of attack by Aston established that most of the common elements are similarly inhomogeneous. Chlorine (35·457) is a mixture of ^{35}Cl and ^{37}Cl; tin (118·70) exists in as many as ten forms, with atomic masses ranging from 112 to 124. These chemically identical species of the same element with diverse masses are known as *isotopes*.

The separation of isotopes has been strenuously attempted by many chemists during the last twenty-five years. There is only one instance where Nature has, in a sense, performed this separation for us—lead derived from uranium disintegrations consists mainly of the isotope with mass 206, while lead derived from thorium disintegrations contains chiefly the isotope with mass 208. In all other cases the proportions of the various isotopes of any particular element appear to be practically constant, whatever the source. Partial separation has proved possible, although exceedingly difficult, in several investigations; complete separation was first achieved in 1933 with hydrogen.

This lecture summarizes, in the main, a series of researches in this field which I and my co-workers have carried out since 1919.

Ionic Mobility

A long-standing controversy has been waged on ionic mobility; one school insisting that ionic mobility is fundamentally dependent upon ionic volume, another being equally confident that it is fundamentally dependent upon ionic mass. The results available in the literature for homologous series of organic anions and cations have been utilized by both parties to prove their respective points; but, since we have no definite knowledge as to what amount of solvent accompanies any ion in its journey towards an electrode, and since it is the *total mass* or *total volume* of the ion and of its accompanying solvent envelope which must be taken into account, such data obviously offer us no means for definitely determining the problem.

The discovery that isotopes possess equal atomic volumes first put us in a position to impose a crucial test, for isotopic ions necessarily *differ in mass*. If mass is influential, therefore, it should be possible to obtain a separation of isotopes by taking advantage of the fact that the lighter ion will migrate more rapidly than the heavier. This idea of an 'isotopic race', however, cannot be carried out experimentally as simply as it might seem at first sight. Ions do not compete under the influence of the electric current in the manner of a track meet, unless we extend our experiences to imagine a continuous relay race. We cannot start all of our ions at one point and obtain a separation by noting when those of a certain species have passed a given goal, for there must be maintained a steady supply all the way from one electrode to another in order for the current to pass, and it will not help us much if a faster ion hurries ahead of its slower neighbour, since it will merely find itself in the company of other slower ions which happened to start a little in advance. By a modification of the experimental procedure, nevertheless, our 'isotopic race' may be converted into a 'parade' which can be suitably regulated.

The apparatus used is shown in the accompanying diagram, and its applicability may be illustrated by a condensed description of the technique employed in the case of chlorine.

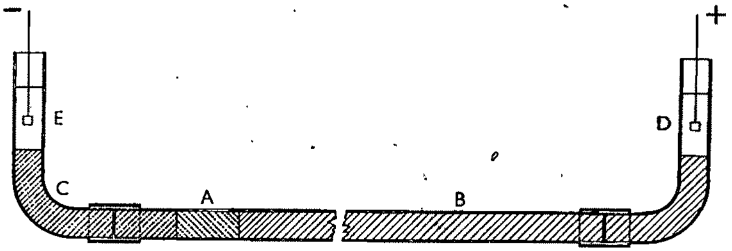

Fig. 1.

An agar-agar gel A containing sodium chloride is inserted as a short middle section in a long horizontal tube of Pyrex glass, one and a half inches in internal diameter. On one side of the chloride gel is added a gel B containing sodium hydroxide; on the other side a gel C containing sodium acetate. The ends of the tube are connected with right-angled Pyrex bends of the same diameter, and the gels continue well up into these bends, as in the diagram. Above the hydroxide gel, after it has set, is poured concentrated sodium hydroxide solution D, and above the acetate gel a solution E of sodium acetate in concentrated acetic acid. Platinum electrodes are placed in these two solutions, and a current is passed through the tube, the electrode in D being made the anode and the electrode in E the cathode. The heating effect of the current upon the gel may be minimized by submerging the tube in a long trough filled with running tap-water.

At the beginning of the run, the boundary surfaces between the various sections of the gel are perfectly sharp. When the current is turned on, the boundaries move towards the anode. Inasmuch as there is a faster-moving ion in front of the chloride ion, and a slower-moving ion behind it, admixture of the salts is absolutely prohibited and the boundaries remain distinct throughout the whole experiment. In order to maintain the width of the chloride section approximately constant, it is well to arrange the concentrations of the various salts in their respective gels in accordance with the transference numbers of their anions. Even if this is not done exactly, however, the boundary concentrations soon automatically adjust themselves to the required ratios.

The rate at which the boundaries move depends upon the potential drop between the electrodes, the length of the tube, and the concentrations of the solutions. In actual practice, the horizontal tube is made up of several three-foot sections connected by rubber bands, and the current is regulated (100–500 volts) so that the boundaries advance about 12–18 in.

---

* From a lecture at the Royal Institution, delivered on May 8.

a day. When the front chloride boundary has almost reached the end of the tube, the apparatus is taken apart. The two rear sections are discarded, two new sections filled with hydroxide gel are inserted in front of the chloride, and new bends are fitted on as before. The chloride ions are now forced to migrate into these two new sections, and the whole procedure is repeated until they have progressed through about 100 ft. of the gel. The chloride gel is then removed from the tube and immediately cut up into strips about 1 cm. in width.

If, now, the isotopic chloride ions with atomic masses 35 and 37 respectively possess significantly different mobilities, the front segments of the gel will contain only the faster-moving and the rear segments only the slower-moving isotope. Preliminary experiments in which a mixture of two sodium salts with anions of known mobilities was substituted for the middle sodium chloride section fully demonstrated this point. Thus, when a mixture of sodium iodide and sodium thiocyanate was employed and the boundary was moved only a few feet, the front segments were found to contain only sodium iodide and the rear segments only sodium thiocyanate. The observed lag of the slower ion was almost exactly equal to that calculated from the difference in mobilities. In this particular case the difference is approximately 16 per cent. In subsequent experiments this difference was narrowed by choosing other suitable pairs of ions: for example, barium and calcium, barium and strontium, and iodide and chloride. The differences in mobilities are here reduced to 8 per cent, 5 per cent and 1 per cent respectively, and the results obtained showed that the method could be depended upon to provide a very considerable degree of separation even at the lowest limit tested.

It was highly disappointing, therefore, to be forced to admit from the results of all our experiments with isotopic ions that no significant separation could ever be detected. The only conclusion that can logically be drawn is that the mobilities of isotopic ions are well within 1 per cent of equality, and that those workers are substantially justified who contend that volume is the decisive factor in determining ionic mobilities. Later theoretical advances, it must be added, support this view, although the matter is still not absolutely settled (Jette, 1927).

Although all the work on isotopes, as has been stated, led to no successful separations, yet the positive results obtained in the test experiments on known mixtures did inspire the hope that the ionic migration method might, after all, prove of practical service in the separation of more familiar materials which are ordinarily obtained by the chemist in a pure state only with extreme difficulty. The most important example of this type is furnished by the family of the rare earth metals. The group of elements known as the rare earths comprises the elements of atomic number 57 to 71 inclusive, and yttrium with atomic number 39. These elements are distinguished by such extraordinary alikeness in chemical and most physical properties, due to the identical arrangements of the two outer shells of electrons in their atoms, that they actually approach isotopes in similarity. It is necessary, in practice, to take advantage of slight differences in solubility observed for corresponding salts and to resolve a given mixture into its components by a long series of fractional crystallizations or precipitations, ranging in number from several hundred to many thousand, according to the elements present and the degree of purity desired. These operations are so laborious and time-consuming that chemically pure samples of individual rare earth compounds are practically unknown, save on the shelves of a few skilled workers in the field of atomic weights. The 'rareness' of the rare earths is due not so much to the lack of abundance of their ores in Nature as to the lack of a simple method for their separation.

The first separation attempted was upon a mixture of yttrium and erbium, kindly furnished by Prof. James, of the University of New Hampshire. Potassium was used as a preceding faster ion and trivalent chromium as a following slower ion. Not only could the position of the rear boundary be more conveniently followed in this particular case because of the colour of the chromic solution, but it was also found possible to observe the actual progress of the separation within the rare earth section in a very simple way by means of a small direct vision hand spectroscope. The majority of the rare earths give solutions with characteristic absorption spectra, and, by noting the increase or decrease in intensity of the most prominent lines in various parts of a section, the experimenter could immediately detect any change in composition in the whole length of the section without interrupting the run. Here yttrium rapidly accumulated in the front half of the section and erbium was relegated to the rear. After a run of fourteen days, during which the boundaries moved two metres, an almost perfect separation had been effected.

The next mixture tested consisted of neodymium and praseodymium, two elements which are so nearly alike that their first differentiation by Otto von Welsbach still forms one of the triumphs of technique in this difficult field. Neodymium salts exhibit a purple solution in water, while praseodymium salts give a green solution. A beautiful crystal of neodymium nitrate and an equally fine specimen of praseodymium sulphate were secured from the Chandler Chemical Museum of Columbia University and the careful work of several years was deranged in a few minutes by mixing these two salts to obtain a solution with an intermediate neutral tint. With this solution as a central section and with the same arrangement as in the preceding experiment, it required only a few days migration to disclose the fact that the front portion of the section was becoming distinctly green and the rear portion purplish. Observation by means of the spectroscope simultaneously showed that the characteristic absorption lines of praseodymium were becoming more pronounced in the front section and fading out in the rear, with the opposite behaviour for the neodymium. At the end of ten days, substantial progress towards a final separation had been accomplished.

Experiments with other mixtures of rare earths showed that, while complete separation could not be secured in every case, yet in most mixtures the mobilities of the ions were sufficiently divergent to compel a very rapid concentration of one particular component in the front or in the rear section. The method may, therefore, be considered as a general new method for obtaining pure samples of the rare earth elements with the expenditure of much less time and trouble than is required by the classical method of fractional crystallization (see, however, Selwood and Hopkins, 1929).

Important industrial uses for the rare earth elements will undoubtedly be discovered as soon as more convenient means for their isolation are developed. Aluminium remained a chemical curiosity until this same end was achieved, and while the later members of the aluminium family may not duplicate the successful career of their brilliant brother, yet it would indeed be strange if Nature had omitted to endow them, alone of all the elements, with no properties of service to mankind.

The success of the experiments with rare earths suggested that the method might be applicable to the separation of radium from barium. The concentration of radium from the barium residues of carnotite ores at present involves a very tedious series of fractional crystallizations, and, since it had already been found that barium could be separated from the other elements of the alkaline earth family by the method here under discussion, it appeared very probable that a similar separation from radium, the last member of this same family, could also be accomplished. Samples of barium residues containing known amounts of radium and of mesothorium (an isotope of radium) were obtained and, after a few days migration, the sections were cut into segments and their radioactivity examined. It was found that the radioactive components of each mixture tested accumulated very rapidly in the front part of the section. The ease of the separation in this case is so striking as to suggest that the ionic migration method may come into technical use for the concentration of radium in barium residues.

An attempt to separate hafnium and zirconium did not lead to such conclusive results. Hafnium exists to the extent of several per cent in all zirconium ores, and the similarity in properties is so pronounced that the actual discovery of hafnium was not definitely established until 1923. A sample of hafnium-rich zirconium oxide was kindly furnished us by Prof. Hevesy. The elements were not amenable to separation by the ionic migration method in the form of positive ions, owing to hydrolysis, and only after considerable search was a suitable negative complex ion discovered in the form of a complex oxalate. After long migration, analysis showed a very slight accumulation of hafnium in the rear of the section, the mobilities of the complex anions being evidently so close together as to render a complete separation impracticable.

The results in an entirely different field have been of better promise. Many of the alkaloids particularly useful for medicinal purposes are derived from natural sources as mixtures of several individual members which can be separated by the ordinary methods of organic chemistry only with great difficulty. The alkaloids, however, are weak bases which form soluble hydrochlorides, and the mobilities of the cations of these salts are not identical. It should, consequently, be possible to obtain a pure sample of an especially valuable alkaloid from the mixture of similar materials with which it naturally occurs by use of the ionic migration method, and several preliminary experiments indicate that the method is indeed applicable in a majority of cases.

Ionic Discharge Potential

Isotopic ions differ only in their minute nuclei, and these are surrounded by a relatively distant cloud of external electrons, increasing in number as we proceed up the periodic system. When an ion is discharged at one of the electrodes during the process of electrolysis, all that happens is that one or more electrons is added to, or taken from, this external cloud. Although, therefore, the free energy changes involved in the discharge of two isotopic ions are not necessarily identical, it is unlikely that the discharge potentials will be markedly different in the two cases, when expressed in volts. If we could pass an electric current through a solution containing two isotopic ions, adjusting the voltage so that the decomposition potential of one species was *just exceeded* while the decomposition potential of the other species was *just not attained*, then a perfect separation should be feasible. Owing, however, to the impossibility of adjusting the voltage with sufficient delicacy, and to the fact that reverse interaction of the discharged material with the solution, unless its immediate withdrawal from the system was effected, would probably tend to re-establish equilibrium conditions fairly rapidly, it appeared that the utmost that would be attainable in practice would be an 'electrolytic fractionation'.

Encouragement that a partial separation might be achieved by this method was derived from the knowledge that it is possible to vary the composition of a tin-lead alloy, obtained by electrolysis of a mixed solution of tin and lead salts, very significantly by varying the voltage employed. The discharge potentials of tin and lead ions differ by approximately 0·01 volts, so that it seemed that there was a likelihood of being able to establish some slight degree of separation of isotopic ions by fractional electrolysis, even if their discharge potentials were still more nearly identical.

The choice of an element to test the method presented great difficulty. Other things being equal, a light element would obviously be preferable, since the external electrons are fewer in number and shield the nucleus less effectively. The experimental obstacles in the case of lithium, the lightest known isotopic element at the time when this work was started (1921), are, however, exceptionally grave, owing to the activity of the free metal and to the elaborate technique necessary for its exact atomic weight determination. Other light elements presented similar objections, and the selection finally fell upon mercury. It is true that mercury is very near the wrong end of the periodic system, its isotopes ranging in atomic mass from 197 to 204, but the free metal is inert and the smallest change in its average atomic weight can be immediately and readily detected by means of density determinations. It was consequently decided to attempt the fractional electrolysis of mercury first, and to continue with lithium later, if the results obtained were sufficiently promising.

The results obtained have been presented in detail in a Ph.D. thesis from Columbia University (Haring, 1924). Electrolysis of an acid solution of mercurous nitrate, using a low voltage and low current density, gave mercury with a density only 0·999981 that of ordinary mercury. This value was the average of fourteen different electrolyses. Parallel experiments in which a high voltage and high current density were employed gave mercury with density unchanged.

The reduction in density, it will be seen, was only nineteen parts per million, which represented three times the average deviation of the individual results. The greatest difficulty encountered in the whole investigation was the exact setting of the mercury level in the pycnometers and, although the error involved thereby was minimized by repeating each setting five times and averaging the results of the five weighings, the probable error involved still amounted to 7·5 parts per million. This fact, together with the disappointingly small change (0·004 unit) in the average atomic weight of the electrolysed mercury, discouraged us from proceeding further at the time.

I have always been convinced, however, of the reality of the fractionation indicated and, in the expectation that more conclusive results would be obtained with a lighter element than mercury, Mr. McLaren of Syracuse University began a systematic study of the electrolytic method of isotopic fractionation under the direction of myself and Dr. Ludlam at the University of Edinburgh in 1930. A considerable amount of work had been done on lithium, but no final results attained, when the discovery of the isotopic character of hydrogen turned our attention early in 1932 to that element, which obviously offered still greater chances of success. Spectrographic evidence suggesting that the proportion of the heavier hydrogen isotope in the first fraction of the electrolysis of water was less than in ordinary hydrogen had been obtained when parallel investigations in the United States were brought to a successful conclusion. The isolation of pure 'heavy' hydrogen and the preparation of pure 'heavy' water from the final fractions of the repeated electrolysis of ordinary water must be regarded as one of the most significant achievements in chemistry in recent years. It is disappointing to have been anticipated, but there is some consolation available in being the first to employ the method by which the separation was made.

Thermal Diffusion

Since 1933, striking advances in the separation of the isotopes of heavier elements have been made, notably by the chemical exchange method of Urey, but perhaps the most promising general line of attack is that opened up recently by the work of Clusius and Dickel on thermal diffusion.

This property was originally noted by Ludwig in liquids so long ago as 1856. Ludwig placed a solution of sodium sulphate in a U-tube, one limb of which was kept in boiling water and the other in melting ice, and found that after two days solid crystals had separated out in the cold limb, while the concentration in the hot limb had decreased to one half. Soret (1879) made measurements of the same kind with various salts, employing vertical tubes with the upper part heated and the lower part cooled, and his results were utilized, not very justifiably, by van 't Hoff (1887) in confirmation of the applicability of the gas laws to solutions.

Thermal diffusion in gases was first discussed by Enskog (1911) and predicted independently by Chapman (1917). In the latter year, Chapman and Dootson achieved a partial separation of a mixture of carbon dioxide and hydrogen contained in two glass bulbs connected by a capillary tube, with a temperature difference of 210°. The theory of the process, both for gases and for liquids, however, remained obscure, as will be evident from the fact that Chapman, in 1929, pointed out that existing theories did not even indicate with any certainty the sign of the slight amount of fractionation generally obtainable.

Only in 1938 did thermal diffusion suddenly come into practical prominence through the astoundingly simple discovery that the substitution of a horizontal for a vertical temperature gradient enhanced the effect to an enormous degree. In the older forms of apparatus, convection currents were deliberately avoided, but Clusius and Dickel ingeniously used such currents to assist the normal thermal diffusion process by what has been called 'thermo-syphon action'.

This action is illustrated in the accompanying sketch, where the convection currents set up in a narrow rectangular vessel with opposite heated and cooled surfaces are indicated by arrows. Normal thermal diffusion establishes a small concentration gradient in the direction *AB*, the concentration of the lighter component of the gas or solution contained in the tube increasing at *A* and decreasing at *B*. The upward convection current consequently causes the ascent of excess lighter molecules, the downward current the descent of excess heavier molecules. A second concentration gradient is thus developed in the direction *CD*, and the steady continuation of the process may ultimately establish, under suitable conditions, a complete separation of the two components of the original mixture.

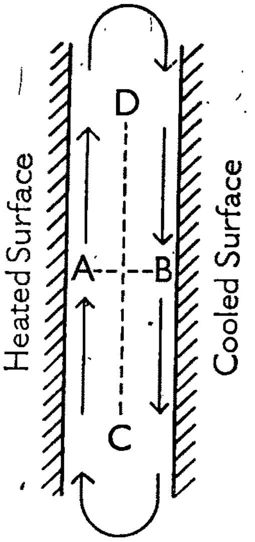

Fig. 2.

An improved form of apparatus devised by Clusius and Dickel for use with gases consists of a long vertical glass tube, externally cooled, with an electrically heated platinum or nichrome wire running down its centre. With a series of successive tubes, altogether 36 metres in length, Clusius and Dickel succeeded in obtaining from ordinary hydrogen chloride top samples corresponding with a 99·6 per cent content of the lighter isotope of chlorine and bottom samples corresponding with a 99·4 per cent content of the heavier isotope. This represents so far the only reasonably complete separation secured by the thermal diffusion method, but the applicability of the method to other cases is obvious.

Considerable work, though practically all of a preliminary nature, has also been done on thermal diffusion in liquids since 1938, and I shall conclude with an account of some simple experiments carried out in my own laboratory by Taylor and Ritchie. The solutions employed are enclosed in a vertical annular space, less than 0·5 mm. in diameter, between two concentric glass tubes, approximately 1·5 metres long. A temperature gradient of about 80° is maintained across this space by the passage of a current of cold water through the inner tube and a current of steam through a surrounding jacket. Eight hours of thermal diffusion of a solution of copper sulphate fractionates it so thoroughly that a goodly crop of crystals will separate out at the lower end, while the characteristic blue colour of the salt will entirely disappear from the uppermost section. Two hours of thermal diffusion of a solution of copper bromide suffices to develop the characteristic reddish-brown concentrated coloration and the bluish dilute colour at opposite ends of the tube. A solution of cobaltic chloride after two hours of thermal diffusion clearly exhibits the deep blue and pink of concentrated and dilute solutions at its upper and lower ends.

It will be evident that thermal diffusion represents a most valuable new tool at the disposal of the chemist, facilitating separations of a most diverse character. One practical point that has already come up for investigation is the influence of thermal diffusion on ingot segregation in steels. Metals are such good conductors of heat that it seems unlikely that any steep temperature gradient could persist for a sufficient length of time in the liquid contained in an ingot mould for thermal diffusion to induce significant segregation. At the suggestion of Dr. C. H. Desch, however, an experiment to test this point was undertaken in my department by Dr. Ritchie. The apparatus employed was similar to that already described, but the annular distance was reduced to 0·25 mm. and the length of the concentric tubes increased to 2 metres. The annular space was filled with a solution of 1·5 per cent zinc (density 7·1) in mercury (density 13·6). Even under such favourable conditions, no fractionation whatever was observable after a run lasting for 32 hours.

This negative result is no doubt largely due to the high thermal conductivity of the amalgam, which reduces the temperature gradient by making the drop between the annular liquid surfaces much less than that between the surrounding glass walls. The same factor, however, as has been noted above, should also diminish the effect of thermal diffusion in ingots. Further work in the field is obviously necessary, but in the meantime the view expressed by Desch that thermal diffusion cannot play an appreciable part in producing the observed segregation in steel ingots appears to be fully justified.

FUTURE OF THE POPULATION OF GREAT BRITAIN

By COLONEL SIR CHARLES ARDEN-CLOSE, K.B.E., C.B., C.M.G., F.R.S.

AN interesting memorandum, entitled "Current Trend of Population in Great Britain", was presented to Parliament by the Minister of Health and the Secretary of State for Scotland in May 1942*, but it is explained, in the opening paragraph, that this memorandum was actually "submitted shortly before the outbreak of the war by the Registrars-General of England and Wales and of Scotland to the Royal Commission on the Geographical Distribution of the Industrial Population". It was not included in the papers published by that Commission. The facts dealt with are those available up to April 1938 and no account is taken of the War.

The memorandum is in the form of a compact little pamphlet of twelve pages, with tables and two diagrams. The account is somewhat compressed and requires attentive study. It brings our knowledge of the facts reasonably well up to the date mentioned, and, with the aid of certain assumptions, gives indications of what our numbers might be twenty or thirty years hence; but it has to be borne in mind that the assumptions do not include the possibility of war.

The main intention of the memorandum is stated to be the presentation of the facts in as objective a manner as possible, so as to correct misunderstandings based on rather sensational forecasts as to what might be the fate of the population of Great Britain a century or so hence. A warning is given that forecasts extending to such a distant future have very slight value.

It is stated that, "as long ago as 1926, attention began to be drawn in official reports to the significance of the phase which the falling birth-rate was then entering". The crude birth-rate, which reached its maximum of 35·4 per thousand of the population in the period 1871–75, after that showed a continuous decline until the year 1933 when it reached the low figure of 14·7, "from which time the fall appears to have been arrested and a minute, though so far uninterrupted, reverse of the movement taken its place". The estimated figure given for 1938 was 15·5, but actually it was 15·1. We can bring the figures up to date, thus: 1939, 14·9; 1940, 14·6; 1941, 14·2. These figures are later than the date of preparation of the pamphlet; they are obviously affected by the War and will not serve as a guide to future peace-time rates, for it must be remembered that great wars, such as the War of 1914–18, or the present War, do materially diminish the populations of the countries engaged in them; the population of Great Britain was probably some two millions less at the time of the census of 1921 than it would have been had there been no war a few years before.

A table is given to show the average annual percentage of increase of our population, and from this it appears that between 1871 and 1911 the average annual increase was 1·12, but after 1911 there was a marked drop and the average increase up to 1938 was about 0·45. The most striking drop was from 0·98 in 1901–11 to 0·46 in 1911–21, that is, the most marked change occurred in the war period "when the rate of increase, which, prior to that time had been of the order of 1 per cent per annum, dropped to rather less than half that figure, at which level it has been maintained ever since".

It is well known that since 1923 the birth-rate has not been sufficient to provide a stationary population; in fact the births are only, by Dr. Kuczynski's calculation, about three quarters of the number required to reach that standard, in spite of the present continued increase of our numbers. Later information puts the net reproduction-rate, in 1938, as 0·84, so that fertility would have had to be raised by about one fifth to result in a stable population. To illustrate the "transitory and unbalanced nature of the present age distribution" a comparison is made between this and two theoretical stationary populations, resulting in each case from a constant annual number of births of 700,000, with different rates of mortality. It is stated that the comparisons show that the population would be maintained at or near its present level of forty-six millions if there were continued the flow of 700,000 births which were registered in 1937. But, of course, the supposition of a continued, constant flow of this kind "could only be realized by a gradual rise in fertility over the next two or three decades". It is added that such a recovery might possibly be secured "with the aid of measures ensuring a national population policy".

The male section of the important group 15–45 is now much smaller than the female section of that group. It is possible that this inequality is not sufficiently stressed by demographers. The marriage-rate must be adversely affected by such a disparity. We all of us know of women who have lost their prospective husbands in the War of 1914–18, and of others who found themselves in a world which contained too few marriageable men. If we think only of the number of marriageable women we shall be apt to forget the question of whom they are to marry. The Registrar-General for England and Wales reported in 1940 that there were more than a million and a half surplus women of marriageable age in the middle of 1939. The present War is not going to make this state of things any better.

---

* H.M. Stationery Office, 1942. 2*d*. net.

An important consideration, too often neglected, is brought forward with regard to mortality. Too often it is assumed that the death-rates at the different ages have improved so much during the past two generations that further significant improvement is unlikely. Here we have clear indications to the contrary. A couple of diagrams are printed which show, in graphic form, the improvement in the death-rates of males and females, not only in the early stages of life, but up to, and including, the decade 75 to 85, in fact, practically for the whole of the normal life of man. In the construction of the diagrams the "death rates experienced in Great Britain over successive decennial periods between 1861 and 1931" are recorded for a series of age groups from 10 to 85. The general character of the curves so obtained is the same for all groups—all show an improvement. The curves have been extended by dotted, free-hand lines, which may be taken to show the probable death-rates at the various ages for the next thirty years. The ordinates (death-rates) are plotted on a logarithmic scale.

The authors are satisfied that this simple way of predicting the future is justified by consideration of statistical continuity, of the effect of curative medicine, and of the fact that some other countries have mortalities lower than Great Britain. It is noteworthy that the Registrars-General should have directed attention to the improvement in British mortality. There has been too much silence on this point on the part of unofficial persons and bodies who have, in recent years, studied the question of the future of our population. The Registrars-General remark that they "find no justification for the assumption, implied in some of the contemporary population forecasts . . . that the most probable course of mortality is one which shows no significant improvement on the rates actually experienced in recent years".

So much for mortality; and now for fertility. The line taken is that there was no diminution of the crude birth-rate in Great Britain after the low level (14·7) of 1933; that there was, in fact, a slight improvement. The values for the five years 1934–38 were 15·1, 15·1, 15·2, 15·2, 15·1. (The figure for 1938 was not actually available when the report was written, and an approximate value of 15·5 was given.) The pamphlet directs attention to the steadiness of the rate during these years, and it is remarked that "it would be unwise and unjustified to assume that any future departure from the present level is more likely to be in one direction than the other". It may here be noted that the Population Investigation Committee, in its publication "The Future of our Population", issued in 1936, put the average crude birth-rate in England and Wales as likely to be 12·4 for the five years 1935–39. This has proved to be wide of the mark.

As for the years 1939, 1940, 1941, the crude rates were 14·9, 14·6, 14·2; but these are war years and the only proper inference is that a world war has a disturbing effect on the birth-rate; this, indeed, is only common sense. The Registrars-General, then, make use of a constant fertility rate. The table on p. 9 of the pamphlet, which shows the effect of applying this rate, is somewhat difficult to follow, but we can accept the statement that the birth-rates were calculated with no bias in one direction or the other. Of course the calculations were made before the outbreak of the War and give no guidance for the war period, which may be a long one.

Since the pamphlet was published there has become available further information, based upon the data provided in accordance with the Population (Statistics) Act of 1938. From this it appears that married fertility has declined since 1921, at all ages of the mothers, decreasing to about two thirds of its previous value at 40–44; and the rate of child-bearing has decreased with the interval since marriage. This change is only explicable by deliberate family limitation.

The final factor dealt with is migration. It is assumed that, since the net outward migration from Great Britain for the years 1924–30 was 1·2 per thousand of the population, and the net inward migration for the years 1931–37 was 1·4 per thousand, that this inward migration would continue "up to 1941, followed by a gradual reduction to vanishing point in 1951, and nil thereafter". This forecast is now, owing to the War, valueless.

With these three factors, mortality, fertility and migration, thus determined, the authors proceed to gather up the results so far as concerns the numerical future of our population. They say that in their calculation there has been no conscious bias in either direction. There is, of course, a margin of uncertainty in the assumptions, and this uncertainty must render distant forecasts increasingly unreliable. But they make allowances for favourable and unfavourable variations in the basic assumptions, and give the effect of a ±10 per cent variation in the ultimate mortality and fertility to be reached in 1971, with proportionate differences in the intervening years. No variation is made with regard to migration. It is added that the forecasts "make no allowance whatever for such change as might ensue from the possible introduction of a controlled population policy in regard either to the birth rate or to migration".

Here are some of the final results:

TOTAL POPULATION OF GREAT BRITAIN (thousands)

Actual population 1937	1941	1951	1961	1971
46,008	46,565 ± 25	47,501 ± 280	47,192 ± 805	45,980 ± 1,579

Taking the lowest figure, we might, but for the War, have expected a population in 1971 of about 44½ millions, in place of the 1937 population of 46 millions. What is a matter of some concern is the age distribution which is shown in the same table. We see that in 1971, according to these calculations, the number of children under fifteen will have come down from 10 millions to 7½ millions; the numbers in the working ages 15–45 will have been reduced from 21½ millions to a little over 17 millions; and the category "over 65" will have increased from 3·9 millions to 7·9 millions. These are the troublesome features of a birth-rate which is insufficient, ultimately, to provide a stationary population. The mere reduction of total numbers might have certain advantages in such a very densely populated country as England. But the overloading of the country with people past work, or, at any rate, not equal to exerting the energy expected of the middle-aged, has no advantage at all.

These calculations would give a date for the attainment of the maximum population some time between 1951 and 1961. An unofficial estimate made in 1927 gave the year of the maximum as between 1949 and 1953. Dr. Enid Charles's estimates, published in 1935, based upon three different assumptions, and very carefully worked out, gave the year of the maximum as 1940, 1944 or 1960. All that we can say is that the maximum has not yet (1942) been reached, and that all estimates have been upset by the War.

We cannot tell how long the War will last, or how many of our young and middle-aged men will be killed or permanently disabled. But we do know that there is the certainty of the War's disturbing effect on the birth-rate, which has already dropped from the recent pre-war average of 15·1 to 14·2 in 1941. Moreover, war takes its chief toll from the young men, and the result must be that the disparity between the numbers of males and females will be still further accentuated, as also will be the ageing of the population as a whole.

To take a long view then, it would appear that, while we need fear no serious diminution of our numbers for the next generation, the population will grow steadily older, and if we wish eventually to attain a happy condition of equilibrium, with a satisfactory age distribution, and thus avoid dangerous decreases of population in the times of our grandchildren and great-grandchildren, we should take steps as a nation, now, to encourage an improvement in the birth-rate.

THE HUMAN FACTOR IN PRODUCTION*

By DR. MAY SMITH

Industrial Health Research Board

THE word 'production', like its fellow 'output', is an uninspiring word. Those of us who must use it for convenience need to remind ourselves at intervals that it is a general term and really stands for concrete things. Behind each article is an innumerable company of human beings, each with his hopes and fears, dreams and realities. This may be a machine age; industry may be mechanized, but personally I have never met the mechanized human being.

The work of any human being, like any other activity, can be affected positively or negatively by numerous causes, and a complicated web has to be unwoven if these causes are to be sorted out. Nor are all of them equally operative all the time; now one, now the other is thrown into relief with the others in the background.

Output is affected by the material and the psychological environments and by the physical and mental make-up of the individual.

Factors in the Material Environment

(*a*) *Lighting.* Natural lighting (daylight) is ideal when there is plenty of it. Since it is not available for night work, and for the ordinary hours of work in winter, and since the black-out has interfered still further, a satisfactory substitute has to be found. With inadequate illumination, output is reduced by a slower rate of working and by an increase of spoilt work. The liability to experience eye strain, 'nervous trouble' (probably irritability) and accidents is increased.

(*b*) *Heating.* Lack of warmth on one hand, and overheating on the other, cause discomfort. Experience gained during the War of 1914–18, and by investigations made since, has shown that efficiency falls when the temperature rises unduly—particularly in heavy industries. In industries such as iron and steel, tin plate and glass manufacture, output is lowest in the hot summer months and highest in the winter. Even in the lighter work of textile operatives, the work deteriorates as the temperature rises above the comfort zone. On the other hand, low temperatures adversely affect manual dexterity. Broadly speaking, those atmospheric conditions which are generally found to be comfortable are also those which are best from the point of view of efficiency and safety.

(*c*) *Ventilation.* The first requirement is an adequate supply of chemically pure fresh air. After that, attention has to be paid to the temperature, humidity and rate of movement of the air. War-time lighting restrictions interfere considerably with ventilation arrangements. When a night shift is worked, arrangements for securing adequate ventilation are even more imperative. The problem of obtaining this adequate ventilation is not a purely mechanical one; there is also a psychological factor.

(*d*) *Hours.* Within limits, an increase of hours will increase the output. The human being is not a machine, and this being so, he can by force of will drive himself to perform far more than he considered his maximum. There were endless examples of this in industry after the Dunkirk period. To do this, however, reserve energy has been used; he has as it were used his reserve energy; and such activity can only be carried on for a limited time, after which considerable reduction occurs. The result is that after a continuous period of overwork, improvement in output does not take place for a considerable time after the return to normal hours. The Health of Munition Workers' Committee of the 1914–18 War summed up thus: "Misguided efforts to stimulate workers to feverish activity in the supposed interests of output are as useless as would be the cheers of partisans encouraging a long distance runner to a futile sprint early in the race."

Even with normal hours of work, the long spells of four and a half or five hours should be broken up, preferably by organized rest pauses and not by accidental interruptions due to waiting for materials, etc. Most people can face with equanimity work of about two hours' duration and can keep a steady pace, but the prospect of five hours' unbroken work often exerts a retarding influence on speed. The effect of any continuous activity, whether physical or mental, is associated with a gradually diminishing success in that activity. The stages at which full success is replaced by partial success and eventually by failure are not the same for everyone, or constant for the same person. Anything that reduces the available energy of the worker, or his interest, will affect the stage at which reduction of effective work begins to take place.

---

* Substance of a paper read on June 6 before a conference on "Social Biology in Relation to the War" arranged by the British Social Hygiene Council.

Fatigue is therefore a relationship between the amount of available energy, the nature of the work, and the attitude of the worker towards it. The remedy for fatigue is rest, and if work has been within reasonable limits, a night's rest will restore energy. If, however, in addition to the effects of hard or prolonged work, rest has to be taken in an air-raid shelter, or rest is impossible on account of the competing roar of guns and bombers, energy is expended instead of being renewed.

Apart from the diminished accuracy and speed consequent upon a fatigued state, there are well-known fatigue sensations, namely, a feeling of weariness, disinclination to make an effort, inco-ordinated movements, organic disturbances, irritability, listlessness. Consciousness of these sensations can distract a worker's attention from the work to himself. Since some of these symptoms are associated with certain diseases, it is not difficult for a fatigued person to think he is ill; the step to being ill is short.

The Psychological Environment

(*a*) *The mental atmosphere.* Diminished efficiency, weariness and an appearance of listlessness *may* still be present when the work is light and hours normal. These pseudo-fatigue effects are due not to the using up of reserve energy but to lack of interest, and are associated with repetitive work, of which there is a great deal; the sufferer is bored.

It must not be assumed that all workers find all repetitive processes boring. One worker will stigmatize a process as boring and find another interesting, whereas to the observer there was nothing to choose between them. It has been found that on the average about 26 per cent of workers experience considerable boredom at repetitive work. An investigation was made into filament winding, soap wrapping, chocolate packing and tobacco weighing, from the point of view of the relation of output and boredom. Results showed that the more intelligent suffered more from boredom than those of inferior intelligence, but there were individual differences, even among the intelligent. It is worth noting that one can be fatigued without knowing it, but not bored.

There are compensations, however, even in repetitive processes, if we consider the worker as a human being and not merely as the performer of a repetition process. Some workers, for example, experience a sense of power when operating a large or delicate machine, and where a machine is a unit there is often a strong sense of possession: "my machine", it is called. Some people find considerable relief in day-dreaming and declare that it makes the time pass quite pleasantly.

Repetitive movements must either be studied as such, in which case they belong to the psychology of habit formation, or else put in their complete setting, including at least the opinions of fellow-workers and authorities about the work, physiological changes, emotional changes, and the general collective life of the place. The total reaction at any one time will be a reaction to a composite situation which constantly changes and of a personality that changes.

(*b*) *Personality of the Authority.* By far the most important factor in the mental environment is the personality of those in authority. There is no correlation between being able to do a job oneself, and being able to superintend others doing it. The effect of power on many people is to let loose a number of qualities otherwise held in check and usually unsuspected; in some occupations it has proved possible to demonstrate the effects of people in authority whose childish emotional development has counteracted their intellectual and practical ability.

There is a price to be paid for inadequate ruling and that price may be the unhappiness of subordinates. Unhappiness, however, does not remain merely a mental state; it receives expression, and in the industrial world this can sometimes be measured, the usual means of expression being an inferior output, high sickness rate or high labour turnover.

In one investigation, four groups of clerical workers were specially selected for experimental purposes to be comparable so far as possible; detailed output records for the six months preceding the experiments were available. Each group was in charge of a departmental head new to the group. Daily records were kept for the next two years. Hence it was possible to compare each person's record during the periods preceding and following the selection. The immediate effect of one head was to increase not only the average output of her group by 10·3 per cent, but also the output of each worker, whereas another decreased it by 5·5 per cent. The work was similar, and the chief difference between the two extremes lay in the temperament of the heads, one being a particularly 'vital' person, the other a person who 'enjoyed' ill-health.

Selection of People for the Right Work

A certain amount of negative selection takes place in most occupations; for example, a thin, weedy man would be unlikely to apply for a dock labourer's job, and a boy with little mathematical ability would scarcely seek to be an accountant. What is less obvious is the need for a much better selection for the majority, and the most important mental characteristic to test for is intelligence. It is now possible, within a very narrow margin of error, to test for general intelligence; it is also possible to differentiate between jobs needing intelligence and those needing little. To allow a person of great intelligence to do a job requiring little is wasteful, both to the individual and to the community; to use a person of lower intelligence than the job requires is to reduce output and cause unhappiness to the individual.

Since the War of 1914–18, when the United States produced the group intelligence test, much work has been done. In addition, a better adjustment of the worker to the work can be obtained by testing for various special skills and by systematic training. Experience in such varying trades as silk-weaving, chocolate covering, metal-polishing, folding and calender work in laundries, has shown that by systematizing movements and by training the novice a saving generally results. If a novice is allowed to pick up his job merely by watching proficients, he frequently adopts uncritically many unnecessary movements, which sometimes interfere with his possible speed and in some cases result in muscular habits harmful to him.

Those who are responsible for the teaching of beginners ought to have made a special study both of the technique of the movements and of teaching. Ability to perform an activity is no guarantee of an ability to teach it.

Time and motion study are a necessary part of the scientific study of skilled movement, and both are as necessary in industrial processes as in sport. If they are used merely to 'speed up' regardless of the individual, they are being used illegitimately and will have serious consequences. Any speed that results in a worker feeling flurried stands condemned. It is one of the anomalies of applied psychology that the earliest attempts to study skilled movement were made by two engineers, Taylor and Gilbreth, whose aim in studying the movements was to reduce the waste of human effort and by so doing to reduce the cost of production and enable the worker to earn more.

Suppose, however, that we know the requirements for a particular activity and that we have tests that are scientifically sound and practicable, and that the people in charge are adequate for the work of supervision. We have even then considered only part of the problem, for no account has been taken of temperamental or emotional differences, and the evidence shows that differences of this nature play an important part in many problems of industrial efficiency, sickness absence and labour wastage. In popular speech, 'temperamental' implies some lack of emotional stability. A healthy minded, well-poised person would scarcely be considered to have any temperament, whereas an emotional, erratic, irresponsible person is generally called 'temperamental'. In practical life, we hear more about temperamental failure than temperamental success. This is due to the nature of temperamental failure, which causes suffering, or at least mild discomfort, to those who come in contact with it.

Throughout history there runs a recognition of the importance of the general emotional make-up of individuals, for health, efficiency and happiness. Many observers, chiefly medical men and Fathers of the Church, that is, those whose work brought them into intimate responsible contact with human beings, have recorded as a fact of observation that there are considerable differences of an emotional nature between people, expressed very clearly in their susceptibility to, and behaviour in the face of, sickness and death, and also in their relation to other people, and as long as we have written records we have attempts at classification. The oldest and best-known comes to us from Galen in the second century, namely, the sanguine, the choleric, the phlegmatic and the melancholic. A more quantitative classification is: (1) those who are emotionally well balanced; (2) those whose temperamental organization is adequate for the duties required, but not altogether perfect; (3) those who are somewhat unbalanced, but within the limits of health, for example, persons rather too liable to be afraid or too easily stirred to anger but not thereby prevented from carrying on; their efficiency and happiness may be impaired but not seriously interfered with; (4) those whose temperamental lack of balance interferes with health.

The 'unbalanced' temperament is the so-called 'nervous' temperament. As a mode of behaviour it has been known for centuries, although not by that name. The name was given in the late eighteenth century and has stuck, though it has long since lost any meaning; the name refers to a mistaken belief that the symptoms characteristic of it were related to the organic 'nerves'. There are no tests for the 'nervous' temperament, and its assessment has to be made by a competent interviewer.

On the whole, after an examination of about a thousand people, there was some evidence showing that the nervous person tended to be less efficient in some environments than others, and also to be more difficult to get on with, to be less satisfied with his work and to have a somewhat higher sickness absence rate. Some environments, particularly those characterized by rigidity of organization and an arbitrary personal criterion of efficiency, are difficult for many nervous people.

The incidence of nervous symptoms varies considerably from one group to another. Those with serious maladjustment ranged from 1·2 per cent in a group of factory workers to 7 per cent in a group of clerical workers.

ABSORPTION AND EMISSION OF RADIATION IN THE ATMOSPHERE

THE radiation traversing the atmosphere is in part radiation coming from the sun, and in part radiation emitted by the earth and its atmosphere. The first is mainly in wave-lengths between 0·25 μ and 2·5 μ ($1\ \mu = 10^{-4}$ cm. $= 10^4$ A.): the second is chiefly confined to wave-lengths greater than 5 μ, and may therefore be called long-wave radiation.

The passage of either kind of radiation through the atmosphere is impeded by Rayleigh scattering, by diffuse reflection from cloud particles, and by true absorption: we are concerned here only with the third of these. The major atmospheric gases, diatomic oxygen and nitrogen, do not contribute appreciably to the absorption, which is due to the presence of small quantities of certain polyatomic gases. Of these, the most important are water vapour (which is responsible for the major part of the absorption), carbon dioxide and ozone. Other gases, such as hydrocarbons, nitrogen oxides, cyanogen and sulphuretted hydrogen, may also contribute to the absorption; their total absorption is, however, small.

Ozone is largely confined to the upper atmosphere; if it were concentrated in a horizontal layer at atmospheric pressure at the ground, the thickness of this layer would be only 3 mm. Carbon dioxide, which is fairly uniformly distributed throughout the atmosphere, would form a similar layer about 2 m. thick. Water vapour is largely confined to the lowest few kilometres of the atmosphere. Its amount is very variable: if precipitated on the earth as liquid water, it would form a layer the thickness of which would range from less than 1 mm. on a cold dry day to a few centimetres on a warm, humid day.

Radiation from the sun is absorbed chiefly by ozone in the ultra-violet, between 0·2 μ and 0·3 μ, and in the visible region, between 0·45 μ and 0·65 μ; and by water vapour in the infra-red, especially between 0·8 μ and 2·2 μ. The ozone absorption results in a hot layer in the upper atmosphere, at a height of about 60 km. Apart from its effect in producing this layer, atmospheric absorption of solar radiation is relatively unimportant; with the sun at the zenith it reduces the intensity of the incident radiation only by 6–8 per cent.

Atmospheric absorption of long-wave radiation is much more important. A layer of damp air one metre thick can absorb one tenth of the radiation emitted from the surface of the earth. Successive layers of the same thickness do not increase the absorption proportionately; the atmosphere is fairly opaque in certain wave-lengths, but nearly transparent in others. When the sky is clear, a quarter of the radiation leaving the earth may pass through the atmosphere without being absorbed. The atmosphere returns to the earth radiation of the wave-lengths which it absorbs. Because it is cooler than the earth, it returns rather less radiation than it absorbs; the radiation returned is, say, two thirds of that emitted by the earth. The quantities of radiation absorbed and returned vary very widely, however, with the atmospheric humidity.

The wave-lengths in which the atmosphere absorbs long-wave radiation can be determined by observations of the transmission of infra-red solar radiation through the atmosphere, such as have recently been made by A. Adel and his co-workers[1]. These show water-vapour absorption in a band between 5 μ and 8 μ, the amount of which varies with the humidity; it is nearly complete between, say, 5·6 μ and 7·2 μ. On one wing of this band, at 7·6 μ and 7·8 μ, there is absorption by nitrous oxide (N_2O) and possibly by nitrogen pentoxide (N_2O_5). Between 8 μ and 13 μ there is relative transparency, broken only by an ozone band between 9·1 μ and 10 μ; at its centre this band absorbs rather more than half the sun's radiation. There are weak absorption lines in the rest of the range between 8 μ and 13 μ, due mainly to carbon dioxide and water vapour, but they normally absorb less than 15 per cent of the sun's radiation in this range. A strong band of carbon dioxide absorption begins at about 13 μ, and cuts off the radiation completely by about 14 μ. This band should end at about 17 μ, but no radiation is actually observed beyond 14 μ. This is interpreted as showing that the rotational band of water vapour, which is known to produce large absorption at great wave-lengths, gives virtually complete absorption down as far as 17 μ. The argument is not altogether decisive, since the sun gives very little energy in these wave-lengths, and a small transmission might evade detection. Unfortunately, laboratory data are inadequate to decide whether the radiation beyond 17 μ is likely to be completely cut off by water vapour or not.

The incompleteness of laboratory data on the total absorption of gases in finite ranges of wave-length is a great handicap to workers in this field. Nearly all the experimental results were obtained before 1920. They do not agree with Beer's law, that the intensity of radiation is reduced in the ratio e^{-km} after passing through a column containing m gm. of absorbing material per sq. cm. of cross-section. Actually the total absorption A varies as a complicated function of m and of the pressure p. For air containing small quantities of water vapour or of carbon dioxide $A \propto (mp)^{\frac{1}{2}}$, roughly, for absorptions between 10 per cent and 50 per cent of the incident radiation; for very small absorptions, $A \propto m$; for large absorptions, A increases much more slowly than $m^{\frac{1}{2}}$. These results are explained by the line-structure of the absorption bands, assuming that the absorption coefficient k_ν due to any line varies with the frequency ν approximately, according to Lorentz's collision-damping formula

$$k_\nu = \frac{i\alpha p/\pi}{(\nu-\nu_0)^2 + \alpha^2 p^2}.$$

If absorption is virtually complete at the line-centres, but line-wings do not appreciably overlap, this gives $A \propto (mp)^{\frac{1}{2}}$; if line-wings overlap, A increases more slowly than $(mp)^{\frac{1}{2}}$; if absorption is fairly small, even at the line-centres, we get $A \propto m$.

The line-width $2\alpha p$ is in general larger when due to collisions with like molecules than when due to collisions with unlike. Thus steam gives greater line-absorptions than air containing the same amount of water-vapour. Steam also gives wider absorption bands than damp air. Absorption at the wings of the bands is by molecules with large rotational energies, and the number of such molecules increases rapidly with increasing temperature. Thus, for example, in the range 11–25 μ, steam absorption is far greater than that of damp air, especially at the short-wave end of the range. This means that the difficulties inherent in the measurement of the absorption of long columns of damp air cannot be avoided by concentrating the water vapour into short columns of steam. Unfortunately, many of the experiments on water vapour absorption were made with steam.

The most complete set of measures with long atmospheric columns is that of Fowle[2], in which absorbing paths up to 200 m. in length were used. Fowle's measures were made with a rock-salt prism, and so are limited to wave-lengths less than 15 μ. Within this range his results agree roughly with those of Adel, quoted above, except, of course, that they did not reveal ozone absorption, which takes place in the upper atmosphere.

Beyond 15 μ, experimental data are scanty. To fill the gap, W. M. Elsasser[3] has recently attempted to calculate the absorption of water vapour from the observed positions and calculated intensities of the absorption lines, between 18 μ and 130 μ. Elsasser uses Lorentz's formula, quoted above, and determines the absorption A in the range in which $A \propto (mp)^{\frac{1}{2}}$. His estimates are subject to several causes of error, and one of his main conclusions, that line absorption is not large at wave-lengths below about 22 μ, is directly contradicted by the observations of Adel and others[4]. Nevertheless, his method is both interesting and suggestive.

Elsasser also predicted, on the basis of Lorentz's formula, that the wings of strong absorption lines near 50 μ would produce a continuous absorption in the region 10–15 μ. Adel obtained results agreeing with this prediction; but Strong[4] has recently set out evidence suggesting that what Adel observed was not a genuine continuous absorption, but a smoothed line absorption. There is no other evidence, experimental or theoretical, that Lorentz's formula is valid as far from the line-centre as Elsasser demands.

The above may serve to indicate how greatly workers on atmospheric radiation are handicapped by the inadequacy of laboratory data on absorption by water vapour. The absorption of carbon dioxide is more easily studied, since a mass of atmospheric carbon dioxide has nearly the same effect as an equal mass of the pure gas at the same pressure and temperature. Ozone absorption has not often been studied, and little is known about its variation with pressure and temperature—an unfortunate fact, in view of the great heights at which ozone absorbs.

Meteorologists have recently attempted to fill the gaps in the laboratory data by measurements on total atmospheric absorption and emission of radiation, summed over all wave-lengths[5,6]. A source of black radiation is viewed through an air column of variable length; the radiation received differs from that leaving the source because of absorption and emission in the air column. If the source is so cold that its radiation is negligible, the emission of the air is directly measurable; this known, the absorption of radiation from sources at other temperatures can be found. The percentage absorption depends on the temperatures T_s, T_a of both source and air; it increases as T_a increases, but decreases as T_s increases, because of the increased importance of shorter wave-lengths, where water vapour absorption is smaller. The emission is equal to the absorption when $T_s=T_a$; considered as a fraction of the black-body emission at the same temperature, it decreases slowly as T_a increases. The results for long absorbing columns do not suggest that there can be any great transparency of water vapour beyond $17\,\mu$.

Brooks[6] has recently indicated how such measures can be used as the basis for a study of atmospheric radiation. He has to ignore the variation of the percentage absorption and emission with T_s and T_a, and to assume that the quantities of water vapour, carbon dioxide and ozone in the atmosphere bear a constant ratio to each other. In theory, it is far better to consider the radiation in the separate wave-lengths; but because of the inadequacy of experimental data, Brooks's method has much to recommend it.

Another question, which has been studied for many years, is that of the total radiation reaching the earth from the atmosphere from all directions and in all wave-lengths. This is most easily studied at night, and is therefore usually called the nocturnal radiation of the atmosphere; it can, however, also be studied during the daytime. The radiation depends markedly on the ground temperature T and the vapour pressure e at the ground. Brunt has found that at any place it is given roughly by $\sigma T^4(a+b\sqrt{e})$, where σT^4 is the black-body emission at temperature T, and a, b are constants the values of which differ, however, from place to place. Brunt suggests that the variation in a and b may be due to differences in the instruments used by different observers; but part may well be due to differences of pressure of the temperature- and humidity-gradients, and of ozone emission.

Strong[4] has interpreted the factor $a+b\sqrt{e}$ in Brunt's expression as follows. At certain wave-lengths, air radiation is due to the emission of carbon dioxide and ozone, and does not vary with e; at others, water vapour is so opaque that it emits like a black body of temperature T, whatever e. Such wave-lengths contribute the term a. At yet other wave-lengths, water-vapour absorption is small and obeys the square-root law (in our earlier notation, $A \propto (mp)^{\frac{1}{2}}$). These contribute the term $b\sqrt{e}$. The explanation is suggestive, but incomplete, since there are wave-lengths in which water vapour is not opaque, but its absorption is too large to obey the square-root law, and these wave-lengths vary somewhat with the zenith distance and the humidity. The factor σT^4 in Brunt's expression also needs explanation, both since the temperature of the emitting air may differ somewhat from T, and because the emission in the wave-lengths at which the atmosphere is opaque need not follow the T^4 law characteristic of a black body emitting all wave-lengths.

Besides depending on T and e, the nocturnal radiation of the atmosphere must vary with the ozone content of the upper atmosphere. The ozone band between $9{\cdot}1\,\mu$ and $10\,\mu$ comes in a range of wave-lengths where the atmosphere is otherwise nearly transparent, and so emission in this band at high levels appreciably affects the radiation reaching the ground. Conversely, radiation leaving the ground is able directly to influence the temperature of the stratosphere because of ozone absorption. Since it receives radiation direct from the ground, ozone tends to produce a higher stratospheric temperature than water vapour and carbon dioxide, which receive radiation from the cold upper troposphere. The effect of the ozone absorption is the more considerable because there is little water vapour at great heights. For this reason, Dobson has suggested recently[7] that stratospheric temperatures may be largely influenced by ozone absorption. His suggestion makes the temperature of the stratosphere depend on the relative amounts of ozone and water vapour present, and explains qualitatively the high stratospheric temperature at the poles, and the advance in phase of the annual variation of temperature in the stratosphere relative to that at any lower level.

OBITUARIES

Dr. C. D. Sherborn

THE sudden death of Charles Davies Sherborn on June 22, within a week of his eighty-first birthday, came as a shock to his many friends. The staff and other workers at the British Museum (Natural History), with which he was continually associated since 1886, will mourn the loss of a distinguished and much-loved colleague, and will sadly miss the inspiration of an outstanding personality.

Born in Chelsea, he was the eldest son of Charles William Sherborn, the celebrated line-engraver and etcher. He received some of his early schooling at the hands of Miss Elizabeth Rye, then a noted educationist, and afterwards went to St. Mark's College School, Chelsea. At the age of fifteen he went into business, first with a bookseller and stationer, and later with a tailor. Then abandoning business for a scientific career, he set off for Switzerland and Germany, and during 1886–87 studied at the University of Strasburg.

At this period of his life Sherborn seems to have been first attracted to the study of geology and palæontology, and worked with Thomas Rupert Jones on the Foraminifera and Ostracoda. His "Bibliography of the Foraminifera" (1888), and his "Index to the Genera and Species of Foraminifera" (1896), indicate the first approaches to what was to become the ruling passion of his life. In 1890, in collaboration with Sir Arthur Smith Woodward, he published "A Catalogue of British Fossil Vertebrata", and at about the same time he catalogued the collections and library of the Geological Society of London, from which body he received the Lyell Fund in 1890. From 1892 until 1899 he was a member of the editorial board of *Natural Science*, and during this period prepared a new edition of a catalogue of the library of the Linnean Society of London. He was invited to examine and arrange the letters and papers of Sir Richard Owen at Sheen Lodge, and assisted in the preparation of the scientific part of Richard Owen's life of his grandfather (1894). Between 1894 and 1908 he undertook a survey of the "White Chalk of the English Coast", in conjunction with the late Dr. A. W. Rowe, and surveyed western Cornwall with Upfield Green. The Geologists' Association, of which he was honorary secretary for nine years, published the results of the chalk survey.

Inspired by the projected "Index Kewensis" for plants, Sherborn put forward in 1890 a scheme for an "Index Animalium", designed to provide a complete list of all generic and trivial names from 1758 to 1850, with a reference to the date and place of publication of each name. This stupendous task, involving the extraction of more than 415,000 references from the original sources, proceeded steadily, and, in spite of a serious breakdown in Sherborn's health during the early stages, the first volume (1758–1800) appeared in 1902. The ten volumes comprising the second section (1800–1850) were published under the auspices of the British Museum (Natural History), and the final part did not appear until 1933—forty-three years after the inception of his self-imposed task!

Sherborn's published papers, many of them of a bibliographical nature, number nearly two hundred, commencing with one on Jurassic fossils in 1886 and ending with his extremely useful booklet "Where is the —— Collection?" in 1940. In addition, his bibliographical work led him to amass copious notes in manuscript, which have been consulted at the Museum by numerous workers and proved invaluable when a catalogue of the Museum's library was prepared by the late B. B. Woodward. He found time to investigate the history of his own family, a labour of love which resulted in "A History of the Family of Sherborn" (1901) and "A Sketch of the Life of Charles William Sherborn" (1912).

Sherborn was an honorary fellow of the Zoological Society of London, and served on the Publication and Finance Committees for many years; an associate of the Linnean Society of London; president of the Society for the Bibliography of Natural History; and an honorary life fellow of the Metropolitan Museum of New York. In 1931 the University of Oxford conferred upon him the honorary degree of doctor of science—a fitting recognition of his life's work.

Such, in brief outline, was the professional career of a man whose liberal culture and diversity of interest and activity were a constant surprise even to those who knew him well. Possessed of a very modest income, and living what to others appeared a most spartan life, he was able to indulge his passion for collecting stamps, coins, books, manuscripts, prints, and antiquities of all kinds. His valuable series of Byzantine coins, on which he was a recognized authority, was presented shortly before his death to the Fitzwilliam Museum, Cambridge, and his prints to the Art Department of University College, London. His many donations to both branches of the British Museum and to other institutions, together with his generous gifts to colleagues and friends, provided a practical expression of one of his most cherished convictions—that objects of special interest or value should ultimately rest in the hands of those who would best appreciate them.

Of the many qualities that endeared him to all, his kindliness, toleration, ready wit and equable temper, and, above all, his abundant generosity, stand out, and few who were admitted to friendship with "The Squire" can have failed to benefit by the association. His ready hospitality to foreign visitors and to other lonely folk provides but one example of his thought for others, and an invitation to "smoke and chat" at his house gave promise of an entertaining and instructive evening. His alleged dislike of women was probably a pose, and those wives of his friends who were lucky enough to gain his friendship soon discovered the kindly and sensitive nature beneath the cloak of gruff misogynism. He was unmarried, and is survived by two brothers.

J. R. NORMAN.

Mr. R. G. McConnell

RICHARD GEORGE MCCONNELL died in Ottawa. Canada, on April 1, 1942, in his eighty-sixth year. His death removed one of the last of Canada's outstanding geological explorers. He was born in Chatham, Quebec, on March 26, 1857, received his B.A. degree from McGill University in 1879 with first-class honours in natural sciences and in 1880 began geological exploration for the Geological Survey of Canada. His first work with the Geological Survey was done in Quebec province, but during 1881–1914 he was engaged every summer in geological studies mainly of reconnaissance and exploratory nature in the west and north-west of Canada. In 1914, he was appointed Deputy Minister of Mines, which position he held until his retirement from the Department in 1921. For several years thereafter he carried on consulting geological work and spent two summers on geological work for the Ontario Department of Mines.

McConnell's field work in the west as an officer of the Geological Survey covered a tremendous area. For five years he dealt with southern Alberta and Saskatchewan, providing much new information on the stratigraphy and coal areas. For three years he studied and mapped the Rocky Mountains west of Calgary, and was the first to recognize and interpret the great thrust faults along the mountain front. For four years he carried on geological mapping in the highly metalliferous West Kootenay area in British Columbia. For a ten-year period his work lay in Yukon, where among many important contributions may be mentioned his study of the Whitehorse copper belt, the Klondike placer field and his persistent recommendations for dredging which were later carried out with considerable profit. For eight years he worked in various parts of British Columbia, dealing mainly with the Portland Canal district, Texada Island, Finlay and Omenica Rivers and Rainy Hollow. For two years he covered ground north of Lesser Slave Lake, including the Athabaska tar sand area. For one winter he remained in the far north, and during the preceding and following field seasons made one of the longest and most remarkable Canadian exploratory trips when he travelled from Wrangell via Telegraph Creek, Dease River and Liard River to the delta of the Mackenzie, returning by way of Porcupine and Yukon Rivers to Skagway. As a result of this trip down through the Grand Canyon of the Liard he was the first explorer to recognize the fact that the Rocky Mountain system ended at latitude 60° N. The results of his field work were published on many geological maps and in some forty reports of the Geological Survey.

McConnell was a fellow of the Royal Society of Canada; he was elected in 1913 and president of Section 4 in 1918. He was elected a fellow of the Geological Society of America in 1889. He became a member of the Canadian Institute of Mining and Metallurgy in 1898. He was also an honorary member of the National Geographic Society.

In November 1898 he married Jean T. Botterell of Montreal. His wife predeceased him by three years. He is survived by a son, Richard, on active service in Africa, and a daughter, Winifred.

He did not seek reward or high position; his ambition was to do the appointed task as well as possible and to further the science of geology. In order to be prepared for any work that he might be called upon to do, he kept himself in excellent physical condition by taking long walks. He took hardships as a matter of course, but nevertheless he could tell interesting stories about them afterwards when surrounded by personal friends, though he invariably declined to tell of his work or experiences on a public platform. After his return from an expedition he would immediately write his account of it in excellent English, and for the rest of the winter or spring would study reports of other geologists to keep up to date in his chosen field. He was fond of the outdoor life, and his keen powers of observation made him an outstanding field geologist. He loved the hills and was reluctant to give up his summer explorations to take on office duties as Deputy Minister. His body was cremated in Montreal and the ashes were scattered over the country he loved so much.

GEORGE HANSON.

Major G. W. Dunkin

MAJOR G. W. DUNKIN, lately director of the Agricultural Research Council Field Station, Compton, Berks, died on March 21 of this year. After postgraduate study, taking the diploma of veterinary hygiene of the University of Liverpool, he settled in general veterinary practice in Kent. Three or four years later, on the outbreak of war in 1914, he joined the Royal Army Veterinary Corps and spent most of his war service in Egypt, latterly commanding the 20th Veterinary Hospital in that country. He returned to practice after the War, but in 1923 was appointed superintendent of the Farm Laboratories Medical Research Council, Mill Hill.

From then on he carried out much important research on animal disease problems, and in this sphere his keen and inquiring mind and his early training and experience enabled him to plan and execute intricate large-scale experiments with domesticated animals and bring these to successful conclusions, avoiding much of the incidental, often unforeseen, complication that can delay and spoil such work on occasion.

Undoubtedly Dunkin's name will be remembered in future more particularly in connexion with the successful investigation into the causation of distemper in dogs carried out in collaboration with the late Sir Patrick Laidlaw. This is a classic in epidemic disease research. Among diseases to which Dunkin devoted much time are Johne's disease of cattle and bovine contagious abortion. He spent years on the study of Johne's disease, particularly with a view to the elaboration of a reliable diagnostic agent and to the production of a vaccine. He obtained important results, and though the problems have not been solved his contributions will be remembered.

In 1937 Dunkin was appointed to the Compton post and the intervening years were devoted to the organization of the estate to suit the requirements of the Agricultural Research Council, and to the inauguration of a large-scale research scheme on bovine contagious abortion.

Major Dunkin was a very active man in many spheres. He had held high office in the National Veterinary Medical Association of Great Britain and Ireland and on the Council of the Royal College of Veterinary Surgeons. He was chairman of the examination committee of that body. He was chairman for some years of the editorial committee of the National Veterinary Medical Association and chairman of a special committee of the Association to investigate small animal euthanasia, an important report being published under his guidance. He held the office of president, Section of Comparative Medicine, Royal Society of Medicine.

NEWS and VIEWS

Sir Henry Tizard, K.C.B., F.R.S.

BY electing Sir Henry Tizard as their president, the Fellows of Magdalen College, Oxford, have made a timely and important break with Oxford tradition, for he is the first man of science to become a head of a college there. When the country can spare him from his present extremely important duties as a member of the Air Council and of the Advisory Council of the Ministry of Aircraft Production, he will return to his old college with a mind enriched by an exceptionally wide and varied experience in the arts of war and peace. He won his spurs in scientific research under the guidance of Prof. Townsend, and his valuable work with Dr. Pye on adiabatic compression of gases made a link with internal combustion engineering which he has maintained ever since. The War of 1914–18 turned his thoughts and efforts to aeronautical research, and he has long exerted a highly important directing influence on British aircraft development, and on the solution of the problems of air warfare, offensive and defensive; these services have stood the nation in good stead during the present great struggle for a free world. The guidance of State assistance to research in pure science and in industry occupied him for eight years between the two Wars, and from that he turned to the administration of scientific and technical education, as rector of the Imperial College of Science and Technology, which has greatly prospered under his leadership. At Oxford, as in London, it is certain that he will not only be successful as head of his College, but also take a prominent part in science, education and national affairs.

Dr. W. S. Gordon

IN the obituary notices in this issue reference is made to the work of the late Major G. W. Dunkin, who was director for the past five years of the Compton Field Station of the Agricultural Research Council. Dr. W. S. Gordon, senior bacteriologist, Animal Diseases Research Association, Moredun Institute, Gilmerton, Edinburgh, has been appointed to succeed Major Dunkin. A graduate of the Glasgow Veterinary College in 1923, Dr. Gordon was on the staff of the Wellcome Physiological Research Laboratories, Beckenham, for some years and took up the Scottish appointment in 1930. At Beckenham he was associated with Prof. Dalling, and other workers in those laboratories, in the production of biological products, and particularly in investigations of anaerobic infections in sheep. In Scotland he has led a team of workers in investigating and dealing with certain sheep diseases, notably louping-ill, tick-borne fever, braxy and lamb dysentery.

At the time of Gordon's appointment, the causal agent of louping-ill had just been discovered at the Edinburgh institute. Dr. Gordon followed up this work, making a close study of the disease and of the filtrable virus responsible for it, and developed methods for the immunization of sheep against the infection. An early discovery in this later work was that two entirely different virus infections were associated with louping-ill, that due to the true louping-ill virus and another, hitherto not recognized, that was named the virus of tick-borne fever, the latter infection being in itself a less severe disease. Among other disease problems on which he has worked in Scotland is grass sickness in horses, and although the cause of the disease is still unknown he has made notable contributions to the literature on the subject. Dr. Gordon has been active in a wide range of veterinary activities in Scotland and has a close personal interest in, and a practical experience of, general farming.

Dr. W. E. Gaunt

DR. W. E. GAUNT has been appointed research director of the Ashe group of associated companies. Dr. Gaunt graduated from the Colour Chemistry Department at the University of Leeds and obtained his Ph.D. for work on biochemistry and physiology undertaken at the Leeds School of Medicine. Afterwards Dr. Gaunt joined Sir John Orr's staff at the Rowett Research Institute to work on nutrition problems, and just before the War went to Guy's Hospital Medical School as dental research fellow to do work of a similar nature. Since the War started Dr. Gaunt has gained further experience in organic chemistry at Guy's, working with Prof. C. S. Gibson, and has also increased his all-round knowledge of nutrition during a short spell with Imperial Chemical Industries Ltd. Dr. Gaunt's experience in several research fields will enable him to serve Messrs. Ashe Laboratories Ltd. in maintaining and extending on sound nutrition lines their numerous food products. We understand that Dr. Gaunt will be encouraged to continue work on fundamental problems, particularly on human protein requirements.

Newton as an Astrophysicist

A PAPER by Elizabeth Connor entitled "Sir Isaac Newton, the Pioneer of Astrophysics" appears as Leaflet No. 158 of the Astronomical Society of the Pacific (April 1942), which supplies a brief outline of the life and work of Newton. Up to the time of entering the University of Cambridge, Newton had not exhibited any extraordinary talent, and though his undergraduate days were profitable, those which followed immediately after he graduated were the most productive which any scientific worker ever experienced. The outbreak of the plague forced him to leave Cambridge, and practically all his time between August 1665 and March 1667 was spent at Woolsthorpe, where his exile allowed him to concentrate on some of his greatest achievements. Among these may be noticed his method of fluxions, the law of the composition of light, and the law of universal gravitation. During this period he gave attention to experiments with the refracting telescope, but because he believed that chromatic and spherical aberration could not be overcome, he turned his attention to the reflecting type.

Towards the end of 1668 Newton completed his first telescope with an aperture of a little more than an inch and a tube 6 in. long. His second telescope was exhibited at the Royal Society in 1672 and is still in the possession of the Society. Its principle was used as the model and forerunner of a succession of giant telescopes which have been constructed since the days of Newton and are still the astrophysicist's best tool. His "Principia" did not appear until 1687 and his real scientific career ended with its completion. Most of his later years were spent in London as Master of the Mint, and he had many honours bestowed on him, but there was no return of the originality of his earlier days. Nevertheless, he gave a considerable amount of time to working over the material in hand. In 1704 his "Optics" appeared and in 1713 and 1726 the second and third editions of the "Principia". Specialists in various branches of science still voice the debt of their sciences to Newton.

Benedict Dybowski

AMONG the Poles whose scientific work was conducted in and for Russia was Benedict Dybowski, a sketch of whose life is given by Dr. J. Borucki in the first issue of *Polish Science and Learning* (June, 1942: Oxford University Press. 2*s*. 6d.). Dybowski was born at Minsk in 1833. As a schoolboy he kept various animals and was apparently the first to observe the metamorphosis of Petromyzon. He studied medicine and biology at Dorpat (1856), Breslau (1857) and Berlin (1860), where he published minor researches, for example, on artificial insemination of bees. At Dorpat again, in 1861, he worked on a monograph of the fishes of the Baltic lands. However, he was arrested for his political beliefs, and though the sentence of deportation was at first revoked, he was sent to Siberia after the 1863 insurrection. Here he began by exploring the forest and steppe around Czyta. Later, at Kultuk, he made long journeys to the Saya Mountains and to Chamar, developing a vast philanthropic medical service among the native population, so that the governor, J. G. Skolkow, invited him to join an expedition to the tributaries of the Amur and Ussuri Rivers, penetrating as far as the Pacific. They had scanty means, having to make their own boats. Nevertheless, Dybowski sent extensive collections to European museums and developed a view that each region showed a special structure of animal life in close correspondence with the environment. He discovered a number of hitherto unrecorded species, including a deer on the Ussuri, and noted the differences between Siberian and Bengal tigers. The birds he collected provided the basis for Taczanowski's critical "Review of Siberian Ornithological Fauna".

With Godlewski, Dybowski spent several years studying the fauna of Lake Baikal, and his researches included biological, chemical, bathymetric and temperature observations. The molluscs and sponges collected at this time were later described in a classical monograph by Benedict's brother, Wladislaw. Dybowski's extensive researches had enabled his friends to secure his release in 1876, but he continued his medical, scientific and humanitarian work in east Siberia. Here he bought horses and reindeer for starving natives and introduced rabbit and goat-breeding into Kamchatka to give the native population a surer livelihood. The last years of his life brought him many honours from his native Poland, for he lived until 1931, dying in his ninety-ninth year. His earnest wish for good relations between the Slav peoples was not realized in his life-time, but his work in this connexion may inspire others to work for the same ideal now that there is close collaboration between Poland, the U.S.S.R. and Czechoslovakia in the many common aims that link them with other lands in the struggle for liberty.

Infant Protection in Mexico

IN an article on this subject in the May issue of the *Boletín de la Oficina Sanitaria Panamericana*, Dr. Salvador Zubirán, Under-Secretary of Public Assistance, states that Mexico is trying to reduce its high infant mortality, which was 30·5 per 1,000 births in 1905 and 122·7 in 1939, by the establishment of child welfare centres which were opened in 1929. In 1937 they were placed under a single Government department, and child welfare became a social as well as a medical obligation of the Government, and lost its 'charity' implications. Important objectives include the integration of the home, establishment of foster homes for deserted children, adoption of orphans, pre-natal training for the mother, vocational training for her if she has to work, and aid from pregnancy until the child is six years old. A children's hospital is being opened in Mexico this year to serve as a centre for medico-social education, scientific investigation and the spread of pædiatric information.

Anthropology in Switzerland

THE *Bulletin der Schweizerischen Gesellschaft für Anthropologie und Ethnologie*, 1941–42, contains a list of members of the Society, a report of meetings held during 1941, and three original articles. Dr. Hans Dietschy advances a number of theories to account for and to explain the attributes and nature of the Aztec pantheon. Dr. Lucia Graf describes some late medieval skeletal remains which were excavated from Holderbank in the Solothurn Canton in 1940, and Prof. Otto Schlaginhaufen provides a very complete anatomical and anthropometric description of four skeletons from Darvela near Truns. Late Iron Age (la Tène period) material was found with these bones. The cranial indexes of the skulls were respectively 76·1 and 74·5 for two male specimens, and 79·4 and 82·8 for two female skulls.

Committee on Synthetic Rubber

SIR ANDREW DUNCAN announced in the House of Commons on July 22 the formation of a Committee to consider the question of synthetic rubber to be constituted as follows: Mr. F. W. Bain, chairman of the Chemical Control Board of the Ministry of Supply (chairman); Sir Edward V. Appleton, secretary of the Department of Scientific and Industrial Research; Dr. J. W. Armit, director-general of explosives at the Ministry of Supply; Sir Robert Robinson, Waynflete professor of chemistry in the University of Oxford; and Dr. F. Roffey, controller of chemical research at the Ministry of Supply.

Earthquake Registered at Kew

ON July 12, a strong earthquake was registered on the seismographs at Kew Observatory. It began recording with *iP* compressional on all three components at 05h. 17m. 47s. U.T. From a tentative interpretation, the *eS* wave registered on all three components (north-south, east-west and vertical) at 05h. 28m. 09s. U.T., which gives the epicentral distance according to the tables in use at Kew as 9,230 km. A full suite of pulses was registered, the maximum ground movement at Kew being 29 μ amplitude at 05h. 53m. 15s. U.T. on the vertical component. The earthquake finished recording at 09h. 05m. U.T.

Announcements

LORD LOUIS MOUNTBATTEN, who is a vice-president of the Institution of Radio Engineers, has given a prize to the Institution, to be known as the Mountbatten Medal; it will be "awarded to the candidate who has proved himself the best candidate amongst those of the Royal Navy or Air Force who have presented themselves for the Graduateship Examinations of the Institution held during the year".

THE British Museum (Natural History), Cromwell Road, South Kensington, London, will re-open to the public on August 1. Owing to shortage of staff and the evacuation of many exhibits, it is possible to open at present only very few of the galleries. The times of opening will be 10–4 on weekdays and 2–4 on Sundays. Small children must be accompanied by an adult or a responsible older child.

THE trustees of the Leverhulme Research Fellowships have approved the following awards for research, tenable for varying periods up to two years: Dr. M. R. Anand, for work on landmarks in Urdu literature; Dr. R. S. Bagnall, for a monograph of the British Apterygota, including springtails, bristle-tails, and other primitive groups; Miss A. M. Cameron, warden, Lady Margaret Hall Settlement, Lambeth, for the study of voluntary social service by wage earners.

WRITING with reference to the review entitled "A Fateful Legacy" in NATURE of July 18, p. 72, Prof. Macgregor Skene points out that the complete quotation from Darwin's "Origin of Species", and indeed the last sentence of the book, is: "There is grandeur in this view of life, with its several powers, having been originally breathed by the Creator into a few forms or into one; and that, whilst this planet has gone cycling on according to the fixed law of gravity, from so simple a beginning endless forms most beautiful and most wonderful have been, and are being evolved."

REFERRING to the obituary of Sir Daniel Hall in NATURE of July 25, Mr. G. M. Johnson, head master, states that the school in which Sir Daniel Hall was so long interested, and in which he did such good work as chairman of the governors, is The Lord Wandsworth College, Long Sutton, Basingstoke, Hants, and not as stated in the obituary notice, at Wantage. Sir Daniel Hall was taking an active part in the life of the College until he entered the nursing home in London, some three weeks before his death.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Distribution of Attack on Iron or Zinc Partly Immersed in Chloride Solutions

IRON or zinc partially immersed in sodium or potassium chloride at first remains unattacked at the water-line. Corrosion occurs at a zone somewhat below the water-line, and researches at Cambridge[1] have indicated it to be connected with the electric current flowing between this zone as anode and a cathodic zone at the water-line, where oxygen, the cathodic stimulator, can most easily be renewed. The corrosion rate has been found to be approximately equivalent, in the sense of Faraday's Law, to this current, which, for solutions of high conductivity, may approach the limiting value given by the interection of the anodic and cathodic polarization curves; for less conducting liquids, it is that value i, which will make an intercept iR, where R is the resistance. Thus the short-period phenomena have been fairly well cleared up. However, the long-period corrosion researches of Bengough and Wormwell[2] at Teddington have shown that finally both metals became more attacked at the water-line than anywhere else. The violent attack at the zone previously immune tended o suggest that the mechanism of corrosion in the later stages was different from that in the early stages; but by introducing the essential distinction between probability and conditional velocity[3], a common explanation appears for the seemingly divergent facts.

If the probability that corrosion will commence at a given point within a time element dt be defined as $p\,dt$, the chance that the point will escape corrosion for time t and then commence to corrode in dt will be $e^{-pt}p\,dt$. The 'expected' corrosion over an experiment asting time T will be

$$\int_0^T e^{-pt}\,pu\,(T-t)\,dt, \quad \text{or} \quad uT - \frac{u}{p}\,(1 - e^{-pT}),$$

where u is the conditional velocity (mass per unit ime and area). This approaches the limiting values of $\frac{1}{2}upT^2$ and uT, as T approaches zero and infinity espectively.

Now p will be minimal at the water-line, since the cathodic product (sodium or potassium hydroxide) is a powerful inhibitor; on the other hand, u will be maximal at the water-line, although it will vary little with level, unless the 'intercept-correction', referred to above, is considerable. Numerous measurements of potential at different distances from the water-line have indicated[4] that the intercept-correction is small, except in very dilute solution; we may expect, therefore, that u will be maximal at the water-line, but that its variation with level will be much less than that of p. Consequently, in the early stages where u and p enter symmetrically into the expression $\frac{1}{2}upT^2$, the expected corrosion will in effect be least where p is lowest, thus explaining the immunity at the water-line. In the later stages, where p does not enter into the expression (uT), the expected corrosion will be greatest at the water-line, where u is highest. Thus we arrive at an explanation of the apparently discordant facts that *the water-line s unattacked in the early stages and severely attacked in the later stages.*

Other possible causes for the severe water-line attack in the advanced stages may deserve consideration, but for the moment the mechanism suggested seems capable of explaining the known facts. The argument just sketched has, however, neglected the possibility that the value of p or u may be shifted by previous occurrences at the same point, or by simultaneous occurrences at neighbouring points. The accumulation of alkali at the water-line (if not dissipated by stirring or by conversion to carbonate) may cause p to fall with the time, thus postponing, perhaps indefinitely, the breakdown at the water-line. Experiments by Dr. T. P. Hoar and by Dr. R. S. Thornhill at Cambridge, largely unpublished, have shown that, if such disturbances be avoided, the water-line will remain immune for long periods (60–90 days). Zinc is more liable to attack at the water-line than iron, while wetting of the specimen above the water-line is found to increase the chance of breakdown, as would, of course, be expected.

Determination of Absolute from Relative X-Ray Intensity Data

IN the 'absolute measurements' of X-ray intensities of reflexions from a crystal, a measurement must be made of the monochromatic radiation incident upon the crystal in one second[1], which, though it can be done fairly conveniently by the ionization chamber method[2], requires a complicated design of apparatus in the use of the rotation photographic method. I have considered the problem in the light of a new synthesis of X-ray data[3] and found that the absolute values of $|F(h)|^2$ may be deduced to a close approximation from the relative intensity data without any further experimental work. The derivation of the equations needed in this deduction in the case of a linear crystal is shown below.

We first assume the relative intensities are known, deduced, in the case of the photographic methods, from the total blackening of the reflexion lines or spots registered on a photographic film. We then assume that corrections are made to these observed data for the various geometrical factors such as the polarization factor, the Lorentz factor, planar factor, and so on. We further assume that we have corrected for the temperature factor. (This assumption is in general not exactly true of course.) The final result is a set of numerical values $H(h)$ which are linearly related to $|F(h)|^2$ by $H(h) = c\,|F(h)|^2$, where c is the constant multiplying factor we intend to determine. For the moment we assume c is known. Then according to Y. L. equation (5) [the notation stands for equation (5) in Yü's letter[3]] we have, $E(h) = \frac{H(h)}{2c\psi(j)^2}$.

If we denote $\frac{H(h)}{\psi(j)^2}$ by K_h for $h \neq 0$ then $E_h = \frac{K_h}{c}$.

We further have $E_0 = \frac{1}{2}\,|F(0)|^2 = \frac{1}{2}\left|\sum_{a=1}^{s} Z_a\right|^2$ (E_0 here and E_h above as well as all the other symbols not defined in this letter have the same significance as in Y.L.). Now let us combine Y.L. equation (2) and equation (4) and substitute the values of E_h and E_0 given above in the resultant equation; we then obtain

$$E(q) = \frac{1}{2}\left|\sum_{a=1}^{s} Z_a\right|^2 \sum_{\mu=0}^{N/2} a_{\mu_0} \cos 2\pi q u_\mu + \sum_{\mu=0}^{N/2} \sum_{h=1}^{\infty} a_{\mu h} \frac{K_h}{c} \cos 2\pi q u_\mu,$$

where $u_\mu = \frac{\mu}{N}$. If in the equation we replace q by an integer k and substitute $E(k)$ by $\frac{K_k}{2c}$, we have, after a transformation of terms, that,

$$c = \frac{K_k - 2 \sum_{\mu=0}^{N/2} \sum_{h=1}^{\infty} a_{\mu h} K_h \cos 2\pi k u_\mu}{\left|\sum_{a=1}^{s} Z_a\right|^2 \sum_{\mu=0}^{N/2} a_{\mu_0} \cos 2\pi k u_\mu}.$$

When $k = 0$, we have,

$$c = \frac{2 \sum_{\mu=0}^{N/2} \sum_{h=1}^{\infty} a_{\mu h} K_h}{\left|\sum_{a=1}^{s} Z_a\right|^2 \left\{1 - \sum_{\mu=0}^{N/2} a_{\mu_0}\right\}}.$$

Since all the quantities on the right-hand side of the last two equations are known, c can be calculated by either of the equations. Consequently the absolute values of $E(h)$ and so of $|F(h)|^2$ are determined. The method might be an approximate one in general due to the approximation involved in Y.L. equation (5). Accordingly, if the absolute values of $|F(h)|^2$ are determined by the existing experimental methods, the present method would provide a test of the approximation involved in Y.L. equation (5) for the crystal in question.

[2] Compton, A. H., *Phys. Rev.*, 9, 29 (1917).

[3] Yü, NATURE, 149, 638 (1942).

Yü's letter[1] on the determination of absolute from relative X-ray intensities suggests several interesting possibilities. His equations might be useful to anyone working with his synthesis[2], but it is possible to devise a method not depending on the quantities $\alpha_{\mu h}$, which are not yet available. The ideal intensity of the *hkl* reflexion is given by

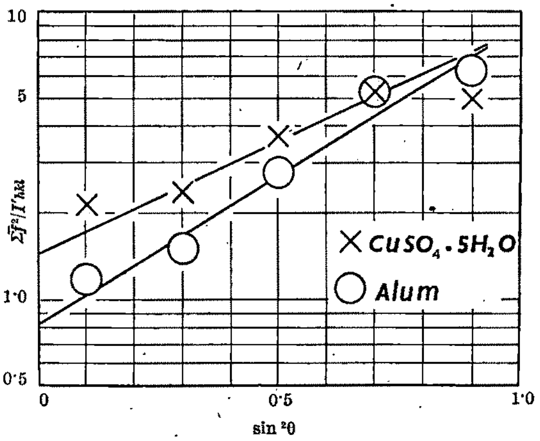
$$\begin{aligned} I_{hkl} &= \sum_{\alpha}\sum_{\beta} f_\alpha f_\beta \exp\{2\pi i[h(x_\alpha - x_\beta) + k(y_\alpha - y_\beta) + l(z_\alpha - z_\beta)]\} \\ &= \sum_{\alpha} f_\alpha^2 + \sum_{\alpha \neq \beta}\sum f_\alpha f_\beta \exp\{2\pi i[h(x_\alpha - x_\beta) + k(y_\alpha - y_\beta) + l(z_\alpha - z_\beta)]\}, \quad (1) \end{aligned}$$

where the f's are the structure factors and the x,y,z's the parameters of the atoms. Suppose that I_{hkl} is averaged for all reflexions in a given range of $\sin^2\theta$. If $\lambda/\sin\theta$ is small compared with the interatomic distances, the exponential terms in equation (1) will take on both positive and negative values, and their average over h,k,l will be practically zero. Then to a close approximation

$$\overline{I_{hkl}} = \sum_{\alpha} \bar{f}_\alpha^2, \quad (2)$$

where the $\bar{f}$'s are the atomic structure factors for the centre of the range of $\sin^2\theta/\lambda^2$.

The experimental value of the intensity of the *hkl* reflexion, I'_{hkl}, will differ from I_{hkl} by two factors a scale factor independent of θ, and the temperature factor. The ratio $\overline{I'_{hkl}}/\overline{I_{hkl}}$ for the group of reflexions will be the product of these. By dividing the reflexions into groups covering suitable ranges of $\sin^2\theta/\lambda^2$ and forming the ratio $\Sigma\bar{f}^2/\overline{I'_{hkl}}$ for each group, the factor $1/c$ required to convert I'_{hkl} to I_{hkl} will be found as a function of $\sin\theta/\lambda$. If the usual form of the temperature factor ($\exp\{-B\sin^2\theta/\lambda^2\}$) is correct, the logarithm of $1/c$ should be a linear function of $\sin^2\theta/\lambda^2$



In normal Fourier and Patterson syntheses it is usual to work only with a zone of intensities, say, the *hk*0's. If two atoms are close together in the projection, they ought to be counted as a single atom with atomic factor equal to the sum of their respective atomic factors. Since in general such coincidences cannot be predicted, there will be an error tending to make the value of $1/c$ too small. In special cases (for example, alum[3], in which the potassium and aluminium atoms coincide in the *hk*0 projection) certain coincidences can be predicted from the space group only, and allowed for.

To test the feasibility of the procedure, it has been applied to the *hk*0 reflexions of alum[3] and copper sulphate[4]. The ranges of $\sin^2\theta$ used were 0–0·2, 0·2–0·4, . . . 0·8–1 (copper radiation), but little reliance can be put on the average for the 0–0·2 group The values of f were taken from the Internationale Tabellen[5]. The logarithm of $1/c$ is plotted against $\sin^2\theta$ in the graph above. The points scatter somewhat, but lie fairly well on straight lines. Since the measurements[3,4] are 'absolute', the values of $1/c$ for $\sin^2\theta = 0$ should be 1. Actually they are about 0·8 and 1·[illegible] respectively. Without further investigation it cannot be claimed that the method is capable of high accuracy, but even that indicated should be usefu in much structure work.

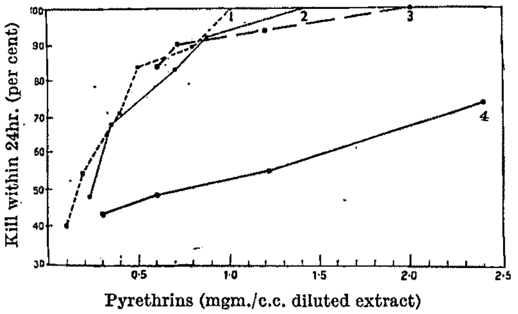
A New Active Constituent of Pyrethrum Flower

THE pyrethrin content as determined by the chemical process is the only factor that influences the market value of pyrethrum, as it is held that a close relationship exists between the amount of pyrethrin present and the number of insects killed. The results of our experiments (see graph) carried out with different samples of pyrethrum, clearly indicate that (1) the percentage kill of insects bears no direct relation to the amount of pyrethrin present in the samples, (2) a smaller amount of pyrethrin extracted from a sample yielding a high pyrethrin value produces better biological results than a larger amount from a poorer sample.



1. PYROCIDE 20. PROPRIETARY EXTRACT.
2. PREPARED FROM *Chrysanthemum cinerariæfolium* (INDIAN); PYRETHRIN CONTENT, 0·702 PER CENT.
3. ,, ,, *C. cinerariæfolium* (JAPANESE); PYRETHRIN CONTENT, 0·602 PER CENT.
4. ,, ,, *C. roseum* (INDIAN); PYRETHRIN CONTENT, 0·247 PER CENT.

It therefore follows from the above that in addition to pyrethrins I and II, the only active constituents so far known, there exists some other toxic principle which operates in the same way as pyrethrin in the production of the characteristic effect of pyrethrum on insects. As the nature of this new substance is not known, it may be designated as *X*. Why a smaller quantity of pyrethrin from a rich sample of pyrethrum produces better results than even a considerably larger quantity extracted from poorer samples may be explained by the fact that the active principle *X* exists in larger amount in the former than in the latter. This also accounts for the fact that a sample of pyrethrum possessing a high pyrethrin content yields better results than another with a lower pyrethrin value.

The results also suggest that the action of the new active principle *X* is not complementary to that of pyrethrin. It is probably an independent body, the growth of which in the flowers is regulated by the same factors as pyrethrin. Both, however, are soluble in kerosene.

The present work confirms our previous finding that kerosene extract prepared from the sun-dried residue left after the removal of pyrethrins I and II from a sample of pyrethrum flowers was found still active, and this led us to arrive at the tentative conclusion that in addition to pyrethrins there were other substances which were responsible for the destruction of insects and mosquito larvæ[1].

For each experiment a hundred flies, *Musca vicina*, all three to five days old, were employed, and our results represent the average of three observations carried out on successive days. The extracts were prepared for us according to the method used for chemical assay[2]. Kerosene was used as the vehicle for diluting the extract; this in itself has not been shown to possess any appreciable insecticidal properties.

The biological variation from the mean calculated from the results of three experiments ranged between 0 and 5 per cent in each instance.

Sample (1) is a commercial standardized preparation known as Pyrocide 20.

A Recording Paper for Field and General Use

AUTOGRAPHIC instruments frequently use a recording paper coated with metallic oxides, on which a black trace is made by a style of copper or silver. While this paper is very convenient, it is not always suitable for field work. To meet the need for a recording paper that would withstand difficult conditions, a special paper has been developed at the Road Research Laboratory. The following details of the process are given in the hope that they may be of use to other workers.

A good quality thin tracing paper, having a smooth surface, is damped and lapped round the recorder drum, the overlap of the paper being fixed with ordinary gum. On drying, the paper shrinks and stretches tightly round the drum, giving a very firm surface with a scarcely perceptible joint. When dry, the paper is spray-painted with a suspension of zinc oxide in dilute cellulose varnish. The resulting surface is pure white in colour, with a smooth matt texture, and on it a hard bronze style makes an excellent black trace.

Drums so coated can be used up to a very high writing speed; a time-base of 300 in. per sec. has been used with complete success, and there is no indication that higher speeds could not be used. The paper surface is strong enough to withstand the style running many times over the same base line without the paper being cut, and the hard bronze style keeps its point very satisfactorily.

In particular, the paper is waterproof, in the sense that rain falling on the paper can be wiped off without affecting the surface. Indeed, records have sometimes been irrecoverable for some days after use, during which period they have been exposed to rain with no damage to the record. It is not desirable to expose the paper to prolonged damp before use, as ultimately the paper absorbs water, swells, and becomes slack on the drum, but an accidental splash does not matter. When damp conditions are likely to be met, the cellulose coating should be rather thicker than is normally used.

After use, the paper is removed from the drum by slitting it with a sharp knife: if the paper is then dry it will come away cleanly from the drum. The resulting records are fully permanent, and will withstand any ordinary handling, filing, etc. They can be written on with pen or pencil, and pencil marks can be erased as with any ordinary paper. The sheets are also sufficiently translucent to allow records to be compared by superposition, or to be measured by putting them over a sheet of strongly marked squared paper.

There is nothing difficult in the preparation of the paper, and a stock of ready-coated drums is a convenience, especially in the rough conditions of large-scale field tests. **A. G. Tarrant.**

The Polygene Concept

Dr. Paul G. 'Espinasse voices[1] misgivings about Mather's polygenic interpretation of selection which are, no doubt, widely felt outside the field of genetics. Each step in the development of genetic theory has given rise to such misgivings. Mather's explanations of his experiments, however, cannot be dismissed as epicyclic (nor for that matter will epicyclic explanations always explain anything). The assumption of polygenes is not even *a priori*. Hereditary properties are very generally known to show mutation, segregation and linkage. Polygenic variability depends on units, factors, elements, or (why not say it ?) genes, which show mutation, segregation and linkage. These are indeed the required criteria. Many important hereditary properties are not individually identifiable. There are hundreds of incompatibility or self-sterility genes known in flowering plants and fungi. Sometimes these genes include only one allelomorphic series, sometimes two. In either case they are not individually but only relationally identifiable. Yet for twenty years no one has questioned the validity of the gene explanations of Kniep and East.

Again, in Œnothera there are complex gene differences the linkage, segregation and mutation of which are responsible for the hereditary properties of a large group of species and their hybrids. The genes responsible are located in particular parts of particular chromosomes. No one has estimated their number. No one probably will do so. But that the particles responsible have the chemical constitution, mechanical arrangement and physiological properties recognized in the genes of maize and Drosophila no one doubts.

The "real methodological difficulty" for Dr. 'Espinasse depends on the polygenes being too small in their individual effects to be separated and counted. This was held to be the real methodological difficulty in the way of accepting the atomic theory. It is the kind of difficulty that arises in the making of any hypothesis. It is a difficulty, however, which is habitually relieved by new discoveries. In this case already it can be slightly relieved. Most plants and animals contain in their chromosomes, apart from the ordinary material which is recognized as carrying the genes of large effect, other parts carrying no identifiable genes. These parts were formerly regarded as inert. Yet they have recently been shown[2] to exercise an effect on cell processes which influences the character of the whole organism. Their influence is so profound as to be less specific than that of the active genes. They are therefore less readily identifiable. None the less they are the demonstrable object of selection, both natural and artificial; and the numbers of genes in them are quite beyond estimation. Indeed there cannot be much doubt that they fulfil the conditions required by Mather's polygenes. This again is a hypothesis. But it is not an epicyclic hypothesis. On the contrary, it shows that coherence with experimental breeding and with chromosome study which is characteristic of genetic theory.

John Innes Institution, **C. D. Darlington.**
Merton, S.W.19. July 1.

[1] Nature, 149, 732 (1942).

[2] Nature, 149, 66 (1942).

May I suggest that the difficulty in respect of the polygene concept, familiar to earlier writers as the theory of multiple or cumulative factors, put forward by Dr. 'Espinasse[1], is rather logical in character than, as he describes it, methodological. In simple genetics the breeding behaviour exhibited in a group of experiments is 'explained' by a few Mendelian factors, the effects of which are sufficiently different for them to be recognized individually. In the case of many quantitative characters the phenomena of heredity open to observation may be 'explained' on the supposition that there are many Mendelian factors having similar, though not necessarily identical effects. In 1918 I was able to show that such a view accorded well with every feature of the phenomena brought to light by the biometrical study of inheritance in man[2]. When Dr. 'Espinasse asks "What is the scientific value of such an explanation ?", the answer is the same in both the cases. Its value lies in its ability to predict the results of future breeding operations.

It is revealing to read: "In order to account for the behaviour in heredity of a variable quality . . . it seems now to be assumed that its behaviour depends upon the distribution of members of several such pairs, of which there may be no independent knowledge". Though the notion is new to him, Dr. 'Espinasse might at least recognize its obviousness and simplicity. The factors postulated are inherited by the same rules which factors investigated independently have been shown to exhibit. They are supposed to be linked in the same systems which have been discovered by the study of individual factors. Does Dr. 'Espinasse find a 'methodological' difficulty in geology when the existence of granite on the surface of the earth leads to the supposition that a similar substance may exist in regions inaccessible to direct observation ?

One of the features to which I directed attention in 1918 is that the hereditary behaviour to be observed does not become more complex as the number of factors is increased. Just as, in the theory of gases the gross behaviour of a molecular aggregate does not depend upon any accidental and momentary configuration of the particles, with its endless complexity, but upon a few constant statistical properties of the aggregate, so it is with the simultaneous action of numerous Mendelian factors. Dr. 'Espinasse's suggestion: "If the number of such pairs invoked as relevant be increased just until they are sufficient to explain the observations", shows a total misapprehension of this situation. In studying the selective response in lint-length of cultivated cottons Panse, for example, has recently exhibited[3] parallel models, some using few (only three) factors, and others an infinite series. The number of factors involved is in fact one of the least influential features of the systems investigated. **R. A. Fisher.**

RECENT ADVANCES IN AMERICAN ARCHÆOLOGY

THE sessions of the first day of the annual general meeting of the American Philosophical Society, held in the Hall of the Society, Independence Square, Philadelphia, during April 23–25, were devoted to a ymposium on "Recent Advances in American Archæology", and were followed by a lecture in the evening by Dr. Sylvanus G. Morley on the work of he Carnegie Institution in Central America and Mexico, to whom the Society's Franklin Medal has been awarded for his investigations in this field.

"The Problem of the Eskimo" was discussed in he opening paper by Dr. Aleš Hrdlička. The Eskimo are one of the largest, still most pure-blooded, and in many respects among the most important of American native groups, and deserve, therefore, all possible scientific attention. They are, moreover, in he flux of a rapid change towards civilization, and all this carries with it, which by itself offers a great interest to the scientific observer. The anthropoogical problem of the Eskimo is not simple. It comprises the questions of their racial identity; their place of origin and antiquity; their relation to the Indian; the modes of their immigration; the reasons of their peculiar spread; the limits of this spread; he cultural history of the people; their physical characteristics; their homogeneity or heterogeneity; their relation to the Asiatic peoples; their relation o the south-western Alaskan groups; the present status of and changes in the Eskimo; their admixure with Indians, with Whites, with Negro; their diseases; and their prospects, demographic and anthropological, for the future.

"The Aztecs: their Cultural and Historical Position in Middle American Archæology" was the subject of a paper by Dr. George C. Vaillant. For various reason the Aztecs occupy an important place n Middle American archæology. They had one of he highest cultures in the Americas at the time of he Conquest. They have been more carefully observed since the sixteenth century than any other ribe in North or South America. In addition, they had their own manuscript records, which are capable of historical interpretation. Thus, from the point of view of achieving the full picture of American Indian civilization, we have more information than for any other part of the Americas.

There seems to have been in the Middle American area first an era, indefinite as yet archæologically, whereby peoples took their first steps toward agriculture. Next follows a long period of sedentary village life based on agriculture. Then came the development of the theocratic State involving pyramid construction, establishment of a pantheon, he creation of some sort of a calendar system and ome type of writing. These traits were developed by a number of tribes who were completely independent racially and linguistically, and there was a onstant type differentiation in style and form in heir handling of these generalized problems. Apparntly, about the eleventh century these ritualistic ivilizations began to collapse, partly from internal causes and partly from external pressure of a military and political nature. The effect of this change is manifested by the presence of Nahua-speaking people diffused over a wide area. As a corollary to this xpansion in Middle America we have in South America the creation of the Inca Empire, the only true empire in the Americas, and in North America evidence of tribal movements strongly affecting the population of the south-western United States and the south-east as well.

Prof. Harold S. Colton presented a "Reconstruction of Anasazi History". This group of prehistoric Indians, who lived on the plateau areas in the South-west, can be divided into six or more separate tribes, each with an independent history. Although all these tribes have much in common, they can be distinguished one from another over a long period of years.

In reconstructing their history, tree-ring studies have furnished a time-scale, calibrated in terms of our own era. Besides this we must recognize the following factors: (1) the persistence of certain culture traits, and (2) the diffusion of others. We must recognize and study the properties of frontiers between the Anasazi tribes themselves and between the Anasazi tribes and the surrounding non-Anasazi neighbours. We must recognize crises in the history of each, dominance or climax as well as the influence of trade and trade routes. From these factors it is possible to reconstruct the history of each separate cultural unit.

Dr. Dorothy Cross described "The Effect of the Abbott Farm on Eastern Chronology". These excavations on the Abbott Farm, along the Delaware River bluff, south of Trenton, New Jersey, have disproved former theories of both a pre-glacial and a clearly defined 'argillite' culture. The artefacts obtained from excavations on the forty-five to seventy-five foot bluff had a vertical distribution similar to that noted on most New Jersey sites, namely, they fall into a normal frequency curve with the peak three to four inches below the 10-in. plough line. No definite levels were discernible, and cultural changes were meagre.

The excavations on the marshy lowlands at the foot of the bluff disclosed three former humus layers, the lowermost 9 ft. from the present surface, separated by virtually sterile layers of sand and gravel. The culture in each humus layer was similar and the human remains showed the same physical type. Pottery of the same texture, surface finish, tempering and decoration was found in all humus layers in the lowlands and at all cultural-bearing depths on the bluff. Although argillite and shale were the most used materials, they were not concentrated at any given depth. Blanks, which were formerly confused with 'palæoliths', were found at all depths and of all materials, including jasper.

Traits diagnostic of certain foci and aspects in regions adjacent to New Jersey are well integrated at the Abbott Farm, and lack the chronological implications they appear to have elsewhere. The Abbott Farm has produced more than a hundred thousand artefacts and potsherds, which, by substantially eradicating negative evidence, may partially account for the uniformity of culture.

Prof. Fay-Cooper Cole's paper, "Chronology in the Middle West", dealt first with the chaotic condition of Mid-Western archæology which existed until a few years ago. Eventually several institutions collaborated in a series of field and laboratory conferences to discuss methods of excavation and fundamental problems, and out of this came the Mid-Western taxonomic system which has brought about systematic treatment of the data.

At present two widespread patterns of culture, with many subdivisions, are recognized and their chronological order determined. Hints of an early pre-pottery horizon occur, then follows an early Woodland, out of which several distinct divisions emerge. Such names as Red Ochre, Black Sand, Central Basin, Lake Michigan, Baumer and Lewis stand for well-established cultural complexes which can be traced over wide areas. Into this situation came influences from the south and south-east which, meeting with Central Basin, produce the Illinois Hopewellian with its spread into Indiana and Iowa. A similar meeting with Lake Michigan appears to produce the Hopewell of Wisconsin. The early stages of the Mississippi pattern are lacking, but the late, fully developed complex with large settlements, truncated pyramids, and a great variety of cultural objects spreads over much of the Middle West. Upper Mississippi extends its influence over northern Illinois, Wisconsin and Iowa, where it continues into historic times as the Winnebago and Ioway Sioux.

Shortly before the coming of the Whites, great cultural shifts take place and the northern Woodland groups, known to the early settlers, become established.

Prof. Willian S. Webb described "Early Horizons in the Southeast". Artefacts typologically similar to those from the Lindenmeir site have been found *in situ* at two sites in Kentucky and in Georgia. These suggest the possibility of a South-eastern Fulsom cultural horizon. While these sites are non-pottery, and all evidence points to considerable antiquity, the absence of stratigraphy leaves their chronological placement undetermined. Deep shell middens on the banks of large streams in Alabama and Kentucky show long occupancy, and a distinctive cultural complex. Sites are either entirely non-pottery or have a non-pottery component at their base. Stratigraphy demonstrates that in Alabama this complex antedates all pottery-making peoples. The material culture complex is dominated by the use of worked bone and antler, and shows the atlatl in use in a variety of forms. Polished stone atlatl weight and large flint projected point are common.

T. M. N. Lewis discussed "Late Horizons in the Southeast". Interpretation of the late archæological horizons in the South-east, he said, is obliged to take into consideration the historical facts concerning the identities, characteristics and distributions of the various Indian tribes at the time of White contact. Even more important than the internal developments of the tribal cultures is the unravelling of the acculturation processes which were operative. The earlier occupants did not always disappear from the region, but tended to be displaced and their cultures modified by contacts with later peoples. Desirable village sites were successively occupied by peoples of divergent cultures and the remains are frequently inextricably mixed notwithstanding the fact that desposits are occasionally deep and stratified.

Three of the widely recognized archæological manifestations of the eastern United States, the Woodland, Hopewellian and Mississippi complexes, are not only involved in the longer perspective of south-eastern prehistory but also represent the important factors in the late horizons. Other more restricted south-eastern elements are also included in the late manifestations of this cultural province.

The chronological sequences of the various cultural entities which have been established in the areas of the South-east, where intensive investigation has recently been carried on, can be reconciled in a general way. These sequences are not always the same throughout this large region, but the majo influences are discernible in comparable chronologica relationships and the interpretations can be coordinated.

The major impediment in applying the Midwester Taxonomic System to the South-east lies not in th principles of the system but in the fact that th determinants for the broader categories, such a pattern, phase and aspect, were set up largely on th basis of northern data or upon limited data fron the South-east.

The most positive ethnic identifications of the protohistoric and historic cultures of the South-east hav been confined mostly to the tribal groups of th Muskoghean linguistic stock, but there are some mor speculative recognitions of cultures of ethnic groups such as the Yuchi, Cherokee and Shawnee, whic give promise of eventual substantiation and acceptance.

Frank C. Hibben read a paper describing "Discoveries in Sandia Cave and Early Horizons in th Southwest". Sandia Cave lies on the east side of th Sandia Mts., some eighteen miles from the town o Albuquerque, New Mexico. Excavations in th Sandia Cave were carried on during 1936–39 an also included tests and explorations in several othe cave sites in the Sandia-Manzano area.

The chief importance of the Sandia site lies in it stratigraphy, which involves an already well-established horizon of early man, the Folsom. The stratigraphic sequence of the cave involves, from the mos recent to the earliest remains, a superimpose stratum of dust and bat accumulation containing i its topmost accumulation a 3–6 in. layer of solidifie calcium carbonate; below the calcium carbonat crust a considerable layer of varying thickness consisting of charcoal fragments, flint chips, bones angular rock fragments, and other cave debris wit intermixed Folsom points, gravers, scrapers, an other implements, indicative of a Folsom horizon below this Folsom cave occupation, a stratum o sterile yellow ochre; beneath the yellow ochre another cave floor with associated debris of bones charcoal, and implements of a shape and manufactur different from the superimposed Folsom varieties these earlier and lower placed points being distinguished by a side shoulder and rougher chipping a compared with the Folsom, and called, from the cav site, 'Sandia points'; below the Sandia level anothe sterile layer to bedrock. This stratigraphy is supported by the included mammal remains, whic indicate that the Sandia and Folsom levels are lat Pleistocene in date, as all large forms are of extinc species, and that the stratum above the calciu carbonate is recent, since only the sloth is found i the lowermost portion of this level.

In another cave in the same region, Manzano Cave additional stratified discoveries were made whic added to the above sequence. Projectile points an bola weights were found in a stratum correspondin to the Early Recent of the Sandia Cave. These projectile points are similar to those of Gypsum Cave On a basis of these discoveries, then, the followin sequence of events concerning the history of th Palæo-Indian may be proposed:

Manzano: Gypsum Cave, camel and sloth association; Early Recent
Wet period: end of Pleistocene.

In a paper entitled "A Possible Cochise-Mogollon-Hohokam Sequence", Emil W. Haury pointed out hat in recent years American archæologists have established several culture groups on hunting and food-gathering planes of subsistence which have been assigned to time levels ranging from about 10,000 to 20,000 or more years ago. Folsom, Sandia, Clear Creek, Gypsum Cave, Lake Mohave, and Cochise remains are a few of the manifestations. While the tendency in these studies has been to push the history of man back into antiquity, refined dating methods, and particularly the development of the tree-ring dating technique, have caused the chronologies of the 'higher', or agricultural people, as for example the Basketmaker-Pueblo, to be revised upward and shortened over previous estimates. An ever-widening gap between the early and the late groups has consequently resulted and doubts have been expressed as to the possibility of establishing any continuity between the two.

An exception to this situation may be found in the southern portion of the South-west, where the Cochise Culture existed. This culture, as reported by Sayles and Antevs, has three recognizable stages, the earliest of which is dated at more than 10,000 years ago, and the latest stage ending approximately 500 B.C., or just before the appearance of pottery and presumably agriculture.

Combining the evidence which has been gathered from open sites and from Ventana Cave, recently excavated by the Arizona State Museum, there are grounds for postulating that the agricultural and pottery-making Hohokam and the Mogollon Cultures have roots which dip into the Cochise complex. Expressed in other terms, the addition of pottery, agriculture, and possibly a few minor traits, to the lithic industry of the San Pedro Stage of the Cochise Culture, produced the earliest known ceramic horizons of the Hohokam and the Mogollon. The early phases of these two groups have much in common, especially ceramically, and it would appear that a common parentage may be claimed.

In a discussion of "Folsom and Yuma Problems", Edgar B. Howard said that satisfactory proof is still lacking to give more than a relative dating for the length of time man has been on the American Continent. Extreme estimates range from about 2000 B.C. to 70,000 years or more ago. The Folsom problem, then, is only part of the broader one dealing with answers to the questions: How long has man been in America? Where did he come from? How did he get there? Before any attempt can be made to answer these questions it is essential to have some understanding of what constitutes a Folsom point and a Yuma point, since reference to these types of spear points appears in every discussion of early man in America.

No matter from what angle the question is approached, one becomes aware of its complexity. It is made up of what appears to be a number of unrelated problems, which, in reality, are parts of the same broad puzzle, namely, man. Many secrets, so far as America is concerned, are locked up in Siberia. Until we know more of the glacial geology, anthropology, and archæology of this region, we cannot hope to answer, with any degree of satisfaction, questions such as that relating to migration routes, the culture stage reached by these early wanderers, and many others which are necessary as a foundation to a real understanding of American prehistory.

L. S. Cressman described "Cave and Lake Bed Cultures of South Central Oregon in the Northern Great Basin": Cave deposits of camp debris separated by pumice have been excavated in south central Oregon. The pumice, which came from the eruptions of Mt. Mazama and formed Crater Lake in the Cascade Mountains, has been given an age of not less than 5,000 and not more than 10,000 years by Dr. Howel Williams. The cultural material above does not differ from that below the pumice except in quality. Caves east of the pumice area contain the same kind of material.

These eastern Oregon caves show the transition from the atlatl or spear thrower to the bow and arrow. Fine twined basketry, the most conspicuous type of article found in the caves, must have been brought in by migratory peoples, for it appears completely developed immediately following a period without basketry. In the eastern caves near the end of the occupation were found a few fragments of coiled basketry. Well beneath the pumice in one of the stratified caves were found chipped obsidian tools, bones of horse, camel and several other genera along with the camp fires used to cook the flesh of these animals.

The bed of an ancient lake has given us three horizons: (1) the oldest, when horse, camel and some elephant-like animal slaked their thirst at the dwindling water holes and were hunted by man; (2) a second, about the shore-line when the lake was beginning to refill about 4,000 years ago; and (3) the historic Modoc culture about the modern shore line, dating from about the beginning of the Christian era.

Analysis of the basketry shows relationship with the culture of the earliest period of Lovelock Cave and the Humboldt Caves of the same region; technological details suggest a relationship with the Basketmaker cultures of the South-west. L-shaped awls made from the scapula of large animals suggest the Oregon - early Lovelock - Basketmaker relationship. Given the lapse of time indicated by the pumice, the Oregon material is antecedent, and perhaps ancestrally related, to certain elements of the classical Basketmaker culture.

In a paper on the "Archæology of the Andean Field", Wendell Cl. Bennett said that Peruvian archæological chronology has long been based on the sequences established by the extensive work of Max Uhle. Only recently has the importance of the Chavin style and culture been demonstrated, although it has long been recognized by such leading Peruvian archæologists as Julio C. Tello and Rafael Larco Hoyle. An examination of the site of Chavin on the River Marañón in the north highlands of Peru reveals a distinctive architectural style, a stone carving style based on the feline concept, and a simple monochrome incised ceramic style. Discoveries on the coast of Peru show similar ceramics at early sites in Ancon and Supe valleys, and more ornate ceramics with incised and relief designs similar to those on Chavin stone carving at many other sites in such valleys as Casma, Nepena, Viru, Chicama, Lambayeque and Piura. These discoveries show that the coast Chavin period is associated with buildings made of rough stone and conical adobes, sometimes with plastered walls elaborately carved and painted. Flexed burials covered with red paint were found by Larco in Chicama valley associated with the Chavin ceramics plus objects of gold, bone, shell, and stone all incised or carved with the typical designs.

A review of the above evidence indicates that:

(1) Chavin is older than any period yet discovered on the north coast of Peru; (2) as a style Chavin has a wide distribution throughout Peru and bids fair to become a third pan-Peruvian period along with the Tiahuanaco and Inca periods; (3) the ramification of styles pertaining to Chavin together with its antiquity and distribution make it one of the basic factors in the revised chronology.

CAUSES OF INTERTIDAL ZONATION

On June 18 and July 9, the Linnean Society of London, under the chairmanship of the president, Dr. E. S. Russell, discussed the causes of the intertidal zonation of plants and animals. The discussion was opened by Prof. T. A. Stephenson, who attempted to elucidate the reasons for both the vertical zonation and the horizontal distribution round the coast of the common intertidal organisms of South Africa, as observed by himself and his collaborators during the years 1931–40 (see Nature, 143, 503; 1939). In his introductory remarks Prof. Stephenson stressed the importance of field observation, as well as that of laboratory and field experiment, for the interpretation of intertidal phenomena, and pointed out also that since much of what is observed between tidemarks is evidently due to the operation of complexes of factors, it is doubtful whether much is to be gained by too great insistence on the part played by each individual factor in a complex. After a review of a number of the factors which may be expected to be concerned in intertidal processes (nature of substratum, desiccation, temperature, wave-action, feeding-habits, competition for food and space, salinity, submergence and emergence, oxygen, carbon dioxide and hydrogen ion concentration, nutritive salts, light and taxes) the conclusion was reached that there is scarcely any factor the effect of which between tidemarks can be imagined which is unable to produce *some* effect on zonation, although certain factors are undoubtedly more important than others; and that the effect of some factors is much more local than that of others. It was further concluded that the principal agent responsible for the *horizontal distribution* of organisms around South Africa is sea temperature; that for *zonation on open rock* the controllers of primary importance are degree of exposure to the desiccation-heat-light complex acting together with degree of exposure to wave action; that for *zonation in rock-pools* the leading factors appear to be variations in temperature and salinity; and that *light* is probably more generally effective in determining the segregation of shade-loving from surface species than in contributing to the actual zonation. In all cases there are subsidiary effects due to causes other than the major ones.

Dr. J. S. Colman next contributed an account of some interesting intertidal enigmas, contenting himself with describing certain distributions for which explanation is urgently needed but which, up to the present time, remain quite unexplained. This contribution brought out very clearly what was recognized by all speakers, that although papers such as those contributed to this discussion introduce "an element of reason into a distribution which could previously best be described as orderly but irrational" (Dr. Colman), yet the rationalizations hitherto attempted are undoubtedly too simple and very fa from being able to explain all the facts observed.

The third speaker, Dr. E. M. Delf, dealt with th significance of the exposure factor in relation to zonation, enumerating its components: this contributio was in line with those of earlier speakers, and adde reinforcement by means of a different selection o details, bringing out once again the fact that intertidal phenomena depend on complexes of interactin factors.

The meeting was then thrown open for discussion and Dr. G. P. Bidder contributed a number of interesting examples taken from among the sponges, som of which threw additional light on points raised by previous speakers, while others introduced furthe features of intertidal life which had not previousl been dealt with. Prof. L. Newton followed with som comments referring to algæ, noting particularly that at least in Britain, the nature of the substratum may become important locally as a factor determining th nature of the flora; and that in past discussions o algal zonation the effects of light had probably been overestimated. Prof. Stephenson, Dr. Colman and Dr. Delf replied briefly to these comments.

On the resumption of the discussion on July 9, Mr. A. D. Cotton, in the unavoidable absence of the author, read a paper by Dr. V. J. Chapman on the horizontal distribution and vertical zonation of marine algæ on rocky shores. Dr. Chapman limited his attention to the common Fucoids. He found himself in agreement with Prof. Stephenson's opening remarks as to the validity of field-work as well as of experiments in the search for the causes of zonation, and also agreed that, of the factors controlling horizontal distribution, temperature appears to be the leading one. Passing to the question of critical levels between tidemarks, Dr. Chapman compared the work of several authors and synthesized their observations for five different localities, concluding that the existence of certain critical levels may be a reality despite undoubted local variations. In an assessment of the various factors the operation of which will render one level more critical than another, the effects were reviewed of mechanical exposure, substratum, submergence and emergence, exposure to air, temperature, illumination, salinity, gaseous exchange and nutrient salts, desiccation and biota. These factors were classified as *causal*, *presence or absence* and *modifying* factors respectively. Lastly Dr. Chapman considered the relation of algal zones to tidal levels in the light of the foregoing review, and pointed out lines along which further progress might be made in the search for the causes of zonation. Mr. Cotton, in reading the paper, added comments of his own referring to matters of detail, but no further discussion took place.

Regarded purely as a verbal discussion, this symposium was disappointing, because, as the result of an unfortunate combination of circumstances, several of those interested were unable to attend the second session of the discussion, and some of them not even the first. At the same time there was a considerable measure of agreement between the views expressed, and the subject was seen to have been somewhat clarified during recent years in spite of universal recognition of its complex nature and of the need for extensive future investigation; and the papers contributed should, when printed in the Society's *Proceedings*, form a valuable reservoir of ideas for the further development of the subject.

T. A. Stephenson.

JUNCTION LINE FILTERS

TWO articles on these filters by F. A. Hinshaw and J. O. Israel respectively (*Bell Lab. Rec.*, 20, No. 9, May 1942) describe their design and applications in communication circuits. Open-wire lines brought into repeater stations or toll offices located in densely populated areas are usually terminated at the outskirts of the area, and the circuits are brought to the office through cables. These cables are usually loaded so as to improve the impedance match between the open-wire line and the cable and to reduce the loss in the cable. At repeater stations and terminals the separation of the carrier and voice circuits is ordinarily accomplished by filters at the office end of the cable. It is not feasible to use the office filters to separate the carrier and voice circuits at the terminal pole to avoid the necessity of carrier loading. Moreover, difficulties would be encountered in obtaining a suitable balance at the voice repeater because of the imperfect impedance match of filter and cable, and of the length of cable between filter and repeater, which would be different for each installation.

These difficulties have been overcome by the development of the junction line filter and its associated networks, the principal duty of which is to separate carrier and voice currents. This separation is accomplished by two single-section filters, a low-pass and a high-pass. As soon as these filters are introduced into the line, however, several other factors become important, the most outstanding of which are longitudinal balance, reflection coefficient, and modulation. Two junction filters are available. In one, the low-frequency channel is wide enough for a 5 kc. programme circuit, while the high-frequency channel is suitable for open-wire carrier telephone systems operating at frequencies as low as 6·5 kc. In the other, the low-frequency channel is wide enough for voice frequencies up to 3 kc., while the high-frequency channel passes frequencies as low as 4·8 kc.

By the use of these junction filters, carrier loading of the longer entrance cable is unnecessary; the voice frequencies are brought in over a voice-loaded pair, and the carrier frequencies over a non-loaded pair. Certain additional equipment is also required. An impedance-matching network on the cable side of the high-pass filter corrects the impedance mismatch that would otherwise exist at carrier frequencies between the filter and non-loaded cable pair. At the office end of the carrier pair a transformer network transforms the relatively low impedance of the non-loaded cable pair to the office impedance. Since with this arrangement the office filters are no longer connected in parallel, compensating networks are required to simulate the impedance effect of one filter on the other.

The insertion of the filter at the terminal pole, however, introduces an impedance irregularity in the voice frequency pair and upsets the balance at the hybrid coil. To maintain a suitable balance, therefore, the effect of the filter and the length of cable must be duplicated in the balancing network. Where loaded entrance cable is connected directly to the open-wire line, the balancing network includes a section to simulate the low-pass filter, a section to simulate the composite set, and a two-terminal network to simulate the impedance of the open-wire line or loaded entrance cable. Where the junction line filter is employed, however, the network must include other elements to simulate both the filter and the particular length of entrance cable involved.

For simulating the transmission characteristics of the entrance cable, which may be of different length for each installation, a series of cable-simulating units has been provided. Three types of simulating networks have been developed and with a suitable combination of them and a suitable amount of building-out, any length of entrance cable can be simulated. Terminal sections are built up in a similar manner to simulate the characteristics of the terminal section.

The ability of the junction filter to operate out-of-doors under all kinds of weather conditions and its comparatively low cost make it an economical substitute for carrier loading on the longer entrance cables. While the junction filter gives transmission results sufficiently satisfactory to justify its use, it does not provide as good overall impedance matching as carrier loading, and it increases rather than decreases entrance cable losses.

'TACK' AND STICKY MATERIALS

AN informal discussion on the subject of 'tack' and sticky materials, arranged jointly by the British Rheologists' Club and the Printing and Allied Trades Research Association, was held at St. Bride Institute, Fleet Street, London, on June 10. Dr. G. L. Riddell presided.

In his introductory remarks, Dr. V. G. W. Harrison said that the purpose of the meeting was to bring together those interested in 'sticky' materials. It is still uncertain what physical properties produce 'stickiness' and it was hoped that as a result of the meeting ideas would be clarified and perhaps some preliminary investigations could be started. Those present represented a wide range of interests, and it was generally felt that an informal meeting of this kind was long overdue.

Mr. C. C. Mill opened the discussion. 'Tack', he said, is a common term in the printing and allied trades. It means, in a general way, 'stickiness', but it has no precise definition and is usually estimated by a 'finger test'. A certain amount of 'tack' is considered essential in printing ink, and it is thus desirable to have some means of defining and measuring this property. Various attempts have already been made. Recently Green (*Ind. and Eng. Chem.* Anal. Edit., 13, 632; 1941) has described a method which attempts to reproduce the finger test. He arrives at an equation in which the time taken to move a mechanical 'finger' a fixed distance is a function of the geometry of the 'finger' system and the viscosity of the material tested.

If Green was really measuring 'tack', Mr. Mill continued, then this property is identical with viscosity, and all liquids of the same viscosity should have the same 'tack', which is contrary to the usual belief. It seems probable that Green over-simplified the problem. In addition to the stress required to maintain viscous flow between the separating surfaces, a further force is required to break the film. This force is dependent on the cohesive and adhesive properties of the liquid, and thus varies from one liquid to another. Another possible factor causing 'tack' is suggested by Maxwell's conception of 'relaxation time'. With an ideal liquid the stress produced by a given strain is rapidly dissipated, but in many real liquids the time taken is much longer; consequently these liquids show elastic properties under certain conditions, and it may be found that 'tacky' materials belong to this class.

If it could be established, Mr. Mill concluded, that 'tack' is due to some combination of fundamental physical properties, it would become possible to devise standard methods of measuring it; but until something more definite is known, it does not seem worth while to continue experimenting along empirical lines. Probably the best way of solving the problem would be to get it taken up as a fundamental research by one of the universities or a research association. Some progress might be made in the meantime by preparing a set of samples with (so far as possible) known physical properties, and submitting these to 'practical men' in the industries concerned for grading according to their own crude tests for 'tack'.

In a written contribution, Mr. J. Pryce Jones said there is slight evidence that 'tacky' liquids possess surface viscosity. He adduced evidence to show that there is no direct relationship between 'tack' and viscosity as measured by a falling ball method. Dr. E. Mardles wrote to say that he has found a fairly close correlation between 'pull resistance' on a flat 'finger' and yield value as measured on a type of Stormer viscometer.

In the general discussion, Dr. G. W. Scott Blair said that 'tack', like 'firmness', may prove to be a *Gestalt*, that is, may display properties other than can be derived from the parts in summation. The terms in such a combination do not always have whole number dimensional exponents; the form of the expression depends on the *Gestalt*, which is itself influenced by the training of the person estimating the property. Usually only one of the terms in the combination (for example, viscosity) is measured instrumentally, and the system is thereby oversimplified, perhaps to such an extent that misleading figures result. A general discussion on the parts which might compose this *Gestalt* followed, in which it was generally agreed that adhesion of the liquid to the testing surface is essential. Fairly high cohesion and viscosity are also important. The 'tack' of some materials (for example, sodium alginate solutions) seems to change with speed; with a rapid motion of the finger, there is little sticking, whereas with a slow rate of break there is distinct 'tack'. The whole problem is complicated by the fact that in the finger test the dimensions of the test sample are continually changing.

Dr. L. R. G. Treloar said that most *spinnbar* materials appear to consist of long-chain molecules in solution or associations of particles, and drawing out these materials produces orientation of the particles, which makes the threads stronger. Small threads are stronger than large because of surface orientation effects. A general discussion followed on whether *spinnbar* materials are necessarily 'tacky', and vice versa. The consistency of potters' clay is judged by 'tack', yet it is not *spinnbar* and does not contain long-chain molecules. Is this 'tack' the same as the 'tack' of adhesives and varnishes? Dr. R. F. Bowles asked whether one can have a 'tacky' solid; if not, is there any limiting viscosity which must be exceeded before a liquid becomes 'tacky'. Mr. J. H. Dawe pointed out that on account of the rapid drying of adhesives, a time factor is important. He also finds it necessary to distinguish between the 'tack' which is just sufficient to keep a label in position on a bottle, and the 'tack' necessary to kee together two surfaces which would otherwise sprin apart.

Finally, it was agreed that, as a start, the Printin and Allied Trades Research Association, in collabora tion with the British Rheologists' Club, should pr pare a set of samples and submit these to experts i the printing ink, paint, adhesive, clay and pottery and plastics trades for grading. Nothing may com of the experiment, but it will serve to show whethe there are any signs that general agreement can b reached, or whether the conception of 'tack' varie from one industry to another. The samples migh also suggest what properties are mainly instrumente in producing 'tack'. The results of the experimen could be considered at a later meeting.

FORTHCOMING EVENTS

Saturday and Sunday, August 1-2

ASSOCIATION OF SCIENTIFIC WORKERS (IN COLLABORATION WITH TH FEDERATION OF AYRSHIRE SCIENTIFIC FILM SOCIETIES) (at Ayr).—Conference on "The Scientific Film and Scientific Film Societies".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on o before the dates mentioned:

GRADUATE LECTURER IN THE ENGINEERING DEPARTMENT—Th Registrar, North Gloucestershire Technical College, Lansdown Roa Branch, Cheltenham (August 10).

LECTURER IN MINING in the Chesterfield Technical College—Th Clerk to the Governors, Technical College, Infirmary Road, Chester field (August 15).

LECTURESHIP IN CHEMISTRY—The Principal, Heriot-Watt College Edinburgh (August 17).

REGIUS PROFESSOR OF ENGINEERING AT EDINBURGH UNIVERSITY—The Private Secretary, Scottish Office, Fieldon House, 10 Grea College Street, London, S.W.1 (September 7).

HARRIS CHAIR OF PHYSICS, University College, Dundee—Th Secretary, The University, St. Andrews (December 31).

LECTURER-IN-CHARGE OF MECHANICAL ENGINEERING—Th Principal, Handsworth Technical College, Golds Hill Road, Hands worth, Birmingham 21.

VISITING LECTURER IN PSYCHOLOGY—The Secretary, King' College of Household and Social Science (University of London) c/o University College, Leicester.

COLONIAL DEVELOPMENT : THE PROGRESS TO PARTNERSHIP

THE selection of speeches by General Smuts which has recently appeared under the title "Plans for a Better World"* makes its appearance at an opportune moment when, as recent debates in the House of Lords and House of Commons on Colonial policy demonstrate, many of the problems which General Smuts discusses, including the idea of trusteeship which he did so much to promote in the mandate system, are coming under close and critical review. The volume includes his presidential address to the British Association at its centenary meeting in London ; an address on science from the South African point of view ; and another address delivered in 1927 outlining his theory of holism. In this glimpse of General Smuts's views on science the volume does something to redress a conspicuous gap in Mrs. Millin's "Life" of General Smuts, and the picture it gives of the wide interests and sympathies of the author, his versatile and imaginative mind is both fair and balanced.

Interesting as is this glimpse of the secret of General Smuts's real strength—and his speeches on the Statute of Westminster, the Commonwealth Conception, his St. Andrews' rectorial address on the challenge to freedom, the Rhodes Memorial Lecture on native policy in Africa read as vividly to-day as when they were delivered ten or even twenty-five years ago, or as those of last year on "Investing in Friendship" and "A Vision of the New World Order" with which the volume closes—it is of even greater interest as illustrating the evolution of outlook and policy which is taking place in South Africa and elsewhere. That evolution is exemplified strikingly in the thought of Smuts himself. Between the views on segregation expressed in his Rhodes Memorial Lecture at Oxford in 1929 and those of his speech at Cape Town in January of this year, in which he admitted the failure of segregation, and of his still more recent "The Basis of Trusteeship", there is no small advance.

The debates in the House of Lords on May 6 and in the House of Commons on June 24 well show the extent to which the War has already shaken conventions and opened men's minds. No one reading the full debates can doubt the reality of Parliamentary interest in Colonial affairs, however much yet remains to be done to quicken interest generally and to arouse public opinion to a sense of its full responsibility in these matters. Mr. Eden's plea for the future development of the Colonial Empire in his speech at Edinburgh on May 8 had already indicated the extent to which the problems of the Colonies are before the Government as it faces the tasks of the future, and the speech of Mr. Harold Macmillan, Under-Secretary of State for the Colonies, on June 24, made it perfectly clear that the policy of the Government towards the Colonies is in no way inconsistent with the high ideals of liberty and justice which have inspired the Atlantic Charter.

---

* Plans for a Better World. Speeches of Field-Marshal the Rt. Hon. J. C. Smuts. Pp. 288+8 plates. (London : Hodder and Stoughton, Ltd., 1942.) 8*s.* 6*d.* net.

The two debates in question followed somewhat different courses. That in the House of Lords put organization and administration in the forefront. In speaking on his motion on the staffing and administration of the Colonial Empire, Lord Trenchard endorsed views earlier expressed by Lord Moyne on the importance of efficient staff to enable the Colonial Office to deal effectively with social problems such as health, education and standard of living, and replan Colonial economics in production and marketing. Lord Trenchard made two proposals. First, he suggested the grouping of the Colonies into not more than a dozen areas, each having a governor-general and a central authority of its own responsible to the Colonial Office. These larger areas are necessary for purposes of defence, economic planning, medical research and the social services. The scheme outlined has points in common with one outlined in a recent *Planning* broadsheet; and in one of the suggested areas—the West Indies—there is already co-operation between Great Britain, the United States and the Netherlands, and in another—West Africa—between the British, French and Belgians.

This suggestion is in harmony with the general tendency towards larger units, and there are many fields in which the precedents of co-operation across national frontiers created during the present War may serve us well in the peace to follow. Lord Trenchard's suggestion is not indeed inconsistent with the continued existence of the smaller unit, which will still have its functions, especially among undeveloped peoples, but it might well provide the means of more effective international collaboration than has hitherto been possible under even the mandate system. In supporting this proposal later in the debate, Lord Hailey clearly indicated that in his view it offers possibilities of building up new and more responsible forms of self-government on the basis of existing local customs and institutions, especially where the units are too small in resources or with little political balance to attain responsible government or the position of a dominion themselves.

Another proposal made by Lord Trenchard was for the establishment of the Colonial Service, at home and abroad, as a single, interchangeable service, independent of the rest of the Civil Service, and that appointments to the Service should be based to a much greater extent on selection. While placing recruitment on the broadest possible basis, he urged that all types of recruit should be given first a year's training in a university which might in time come to be regarded as specially concentrated on Colonial interests. Lord Trenchard also advocated outside recruitment at the top of the Service, and warmly welcomed Sir George Gater's appointment to the Colonial Office. He also endorsed Lord Moyne's proposals for proportional pensions to facilitate retirement of Colonial officials.

Two other recommendations were advanced by Lord Trenchard as even more vital: first, the establishment of a Colonial Advisory Board, and, secondly, a Colonial Staff College to which the abler and more promising men in the Service would be drafted for a course at the age of about thirty-five. The aim would be to bring them in constant contact with each other and with the outside world, to broaden their outlook, and to stimulate their enthusiasm so as to encourage a progressive and constructive spirit Furthermore, Lord Trenchard looked to a representative Colonial Council to stimulate and focus public interest in the Colonies and bring informed opinion to bear upon them.

Generally speaking, Lord Trenchard's proposals were well supported in the debate which followed Lord Moyne considers that recruiting should be very much on the lines suggested, and he and Earl De La Warr, and also Lord Hailey, stressed the importance of bringing the largest possible number of native-born Africans and other Colonials into our Governmen services. Lord De La Warr pointed out that in great portions of Africa education and health must be treated as one subject, but in place of a Colonia Staff College he suggested a system of travelling scholarships. He stressed, too, the importance of more enterprise and courage in administration, more attention to the right political development, to the things that are the foundation of life, the intelligence, health, food and economy of the native African population. The Colonial staff should be chosen organized and trained with that essential purpose in mind.

In Lord Hailey's tribute to the present capacity of our Colonial Services, he, too, emphasized the need for men capable of dealing with economic problems, an aspect which has hitherto received insufficient attention in the Colonial Service, but he agreed with Lord De La Warr as to the high quality of some of the younger and more recent recruits. Lord Hailey doubted whether a fully interchangeable service is desirable, although he believes that interchangeability would do something to enhance the position of the Colonial administrative service and that the Colonia Office would gain substantially through the presence of a much larger number of men with actual experience of executive work and its requirements. In his view, the ideal would be to have a staff in the Colonial Office composed partly of men from the Colonial administrative service and partly of men who have had experience in other departments of Home Government, officered by the home Civil Service and departments, which deal with so many activities, social and economic, now forming an increasing part of the work of the Colonial Office Lord Hailey insisted once more on the importance of the conception of the State as the chief agency for social welfare, which, forcing its way into Colonia politics, is giving us a new and more constructive and beneficial interpretation of trusteeship without diminishing its moral quality.

Viscount Elibank, in supporting the idea of a Colonial Staff College, advocated, not so much the refresher courses, as selection at an earlier age on the lines of the selection of Rhodes Scholars, while Lord Faringdon, referring to the friction between technica and administrative services which is liable to arise under the selection system of recruitment if the administrative service holds a superior position believes that a college to which all aspiring Civil servants should be sent would meet the difficulty, and he supports the idea of refresher courses.

Lord Trenchard's speech was welcomed by Lord Cranborne, who in replying for the Government stressed the dynamic character of the British Empire. While interchangeability could not be so somplete in the Colonial Service as it is in the Diplomatic Service, the desirability of the fullest possible mobility is fully recognized in the Colonial Office, especially in the technical branches of the Service where mobility is easier. Lord Cranborne stated that he intends to see that there is the greatest possible measure of interchange between the Colonial Service and the Colonial Office, and that this is one of the reasons for the appointment of Sir William Battershill as Deputy Under-Secretary and of Sir Cosmo Parkinson as his personal representative to maintain contact with the governors in the Colonies.

In regard to recruitment, the procedure proposed by Lord Trenchard is already largely the normal. Lord Cranborne hopes that selection on merit will remain the Colonial Service system of entry, and he does not believe that any alteration is necessary in the system of selection. The Colonial Office is already studying methods of improving the training of both the technical and the administrative services, and the idea of a further course of one or two years training for those who have had several years experience in the Service is under consideration. Lord Cranborne also warmly welcomed the idea of giving the Government powers of compulsory retirement of officers before their time is up, so that dead wood could be cut out. He promised full consideration of the suggestion of a Colonial Staff College; but he is dubious about the proposal for a Colonial Advisory Council and believes that advice should be given in Parliament and not by an officially appointed body. As to recruitment by bringing in new blood at the top, while that is often done, much harm could come to the Service if too frequent use be made of such powers by the Secretary of State.

The whole debate in the House of Lords remained at a high level, and in his closing remarks Lord Cranborne emphasized the importance of the right spirit pervading and inspiring policy and machinery. Without a moral and ethical basis, no Colonial Service could achieve what it set out to do and our Empire would not deserve to survive. That note was noticeably lacking in the House of Commons during the debate on Colonial affairs on June 24, which was indeed of a different character.

Mr. Harold Macmillan's speech was mainly concerned with the short-term aspects of Colonial affairs, in the course of which, however, he paid special tribute to the work of the Economic Department of the Colonial Office, which has been extended. In looking to the future, he developed the same outlook as Lord Cranborne, stressing the necessity for understanding and friendship as a basis for partnership. Changes or preparations for changes in the Colonial Service should have two chief aims: first to provide increasing opportunities for the people of the Colonies to fill posts in the public service of their own countries; and second, to provide a mobile force of highly qualified experts in administration, in science, in agriculture, in mining, etc., at the command of the Secretary of State to be posted wherever in the Colonial Empire they were most needed at a particular time. The unification of the Colonial Service which has been proceeding since 1930 is to be taken a stage further for this purpose in accordance with proposals initiated by Lord Moyne which are being worked out in consultation with the Colonial governors.

Mr. Macmillan then urged that our development policy should be considered as a whole and not in single compartments, and he went on to describe the various technical advisory committees which have already been appointed, of which the most recent is the Colonial Labour Advisory Committee. Special reference was made to Lord Hailey's services in the organization of research, which must cover economic ends as well as nutrition and education, etc. To promote the increased prosperity of the peoples in the Colonies scientific research must be applied to market needs. In the long run, the standard of living and the expenditure on social services in the Colonies depend on their economic prosperity, and the Colonial Development and Welfare Act is regarded as the instrument for long-term planning. Large-scale public investment on public needs will be required, and we should now prepare the plans and priorities for capital development so as to be ready to advance our demand for a fair share of reconstruction work for the Colonies.

It is clearly recognized by the Government that systems of government or administration alone are not enough; they must be supported by vigour, decision, imagination, ruthless and overriding zeal. That view was reflected in the subsequent debate, in which a proposal for a Colonial Development Board was strongly advocated by Capt. P. D. Macdonald and Squadron-Leader P. W. Donner. Pleading for a new conception of Empire, Capt. Macdonald suggested that the proposed Board should be a statutory body under the Secretary of State for the Colonies, and in addition to a representative of the Chiefs of Staff Committee, it should include full-time members for economy and finance, health, education and housing, and all the supply departments, with power to co-opt from outside on special sub-committees. It would take over the Colonial Development Fund, and Capt. Macdonald stressed the opportunity for real statesmanship and for adequate financial resources. The five millions of the Colonial Welfare and Development Board should, he suggested, be used to pay the interest on the far greater loan of two or three hundred million pounds which is really required to tackle on an adequate scale the problems confronting us.

Squadron-Leader Donner suggested that the Colonial Development Board should have the four principal functions of the Imperial Development Board suggested by the Royal Commission of 1917. It should promote first new sources of supply, and secondly new measures for the prevention of waste; thirdly, it should investigate the possibility of finding substitutes, and fourthly, would stimulate scientific research. Recalling the weakness of the Colonies in regard to research—a position on which the Royal Commission had commented—Squadron-Leader Donner said that our Colonial administration has been weakest in dealing with economics and development.

Mr. Macmillan promised to examine the suggestions carefully, and while dubious as to the desirability of establishing the particular organization suggested, recognized the importance of study and research as a basis for policy. Instruments for making and executing plans must be included, and some continuity of policy preserved in capital development in future. In regard to the suggestion for an assurance in realistic and convincing terms, pointing the way to freedom, equality, responsibility, and the reconstruction of Colonial economic and social life, Mr. Macmillan referred to the Joint Declaration and the Prime Minister's explanatory comment.

Though it could not be said that the debate touched the high level of that in the House of Lords, it is clear that many members of the House of Commons are alive to the grave issues and responsibilities involved. Mr. R. W. Sorensen made several valuable suggestions. We should see that the whole of the Colonial Development Fund is expended on development, if not in the particular year allocated, then in the following year. Friendship between the black peoples and ourselves should be fortified by a comprehensive scheme of educational development. Our medical services also require drastic development, and if enforced labour is required, we should see that the finest conditions that can be secured are granted to the people. Finally, we should consider drawing up a plan of constitutional and political development in West Africa as well as in the West Indies.

The emphasis which is rightly being placed on economic development as the basis for Colonial stability and prosperity, and on international co-operation in the attack on such problems as soil erosion and tropical diseases, if adequate technical staff is to be available, should not lead us to overlook the importance of some of the other basic conditions and principles inherent in the idea of trusteeship or partnership between the peoples of the world on which the Atlantic Charter is based. It is not solely a matter of more imagination and creative insight in fostering the growth of self-government through new institutions more adapted to Colonial conditions than the outward forms of British institutions. Equally with economic development must come educational development, not merely of the few who must be drawn into the active conduct of affairs, but also of the many, so as to eliminate the psychological errors, misunderstanding and apathy that have thwarted in the past well-meant but erroneously conceived administrative measures. In this we must, as Mr. I. L. Orr-Ewing pointed out in the House of Commons, redress our failure to popularize education among African women, and also the tendency to excessive concentration on book-learning in education. We must educate the African to be a good African and not a mediocre European, and to develop on his own traditional lines.

That the pre-war official or accepted conception of Colonial policy is now inadequate as a guide can scarcely be questioned. The two principles of fulfilment of the obligations of trusteeship and of assisting the dependent units of the Empire to attain self-government are not really definite enough. The first is negative rather than positive, corrective rather than constructive, and, as Lord Hailey has pointed out, its moral standards are liable to too many interpretations to be a satisfactory guide. The inadequacy of the second was fully exposed in the House of Lords debate, and if we are to bring new life and strength into the system the first step may well be, as Lord Hailey suggests, the restatement of our relations not as between trustees and wards, but as senior and junior partners, on terms which recognize that the latter must as of right acquire an increasing share in the control of our common undertaking. Moreover, as we apply to the Colonial empire the conception of the State, not merely as an agency for maintaining justice or preventing abuse, but also as the most active agency for promoting social welfare and improving the general standard of living, our obligations to the Colonial peoples become not those of trustees but those incumbent on the modern State in regard to the improvement of the social services and the standards of living in its own backward areas.

That shift of emphasis in itself should prove a powerful solvent of misunderstandings and friction. By the stimulus it gives to the self-respect of the Colonial peoples it should promote the more rapid development of representative local institutions, and the full participation of the people of the country in their own administrative services. Moreover, building firmly on the basis of existing institutions so as to assist the evolution of forms of self-government best suited to the traditions and circumstances of the people should also assist in that co-operative attack on the great problems of health, nutrition and the conservation as well as development of natural resources, which will be essential on an international scale as well as within the bounds of our own or any other Colonial Empire.

CYNIC SCIENCE

The Scientific Life

By Dr. John R. Baker. Pp. 154. (London: George Allen and Unwin, Ltd., 1942.) 7*s*. 6*d*. net.

DIOGENES had only one request to make of Alexander: "Keep out of my sunlight". Insolation, to the Cynic, was what the bath, the omnibus, and the tea-tray have been to eminent physicists and chemists; and in a world overshadowed by a planned technology, Dr. Baker takes up the cause of individual freedom for men of science.

That technology is something quite distinct from science, as we understand it, Dr. Baker has little difficulty in showing. That a planned technology, which is essential and inevitable in a time of national crisis, necessarily threatens the freedom of scientific discovery, is less easy to prove. He notes unfavourable portents. The capital letters in the Wordsworthian motto of NATURE were deranged "about 1935"(p. 130), but this the Editors may restore, or replace by lower-case, which is always in anti-capitalist majority. [The change was made on the representation of scholars in order to make the quotation conform with the accepted Wordsworth text.—EDITORS.] The British Association has held a conference, and published a "Declaration of Scientific Principles" which amplified (without transgressing) its century-old commission "to give a stronger impulse *and a more systematic direction* to scientific enquiry, and to obtain a more general attention to the objects of Science, and a *removal of any disadvantages of a public kind* which impede its progress". M. Maisky has stated that "we in the Soviet Union never believed in so-called 'pure' science. We always believed that science must help humanity in its needs", in the course of an appeal which we may hope is unnecessary here, to put "first things first" in a dangerous emergency.

Dr. Baker gives entertaining and picturesque examples of the personal habits of men of scientific genius, which might be capped by those of great artists, poets, and other unusual people. Some great soldiers—and other 'planners'—have also exhibited their need of freedom. But this is the 'common-sense' or 'magical' argument which he ridicules (pp. 115–16): to make his proof secure, as one man of science to another, he must be asked to give negative and crucial instances. He does not seem to extend his protest against the use of men of science in technological research to the employment of them in another useful art, education. Indeed he carries compromise so far as to admit that teachers of science may be required to lecture punctually and on prescribed subjects, and members of a research institute to co-operate in its programme of research. It is not so long ago that the Association of Scientific Workers was upholding the right of teachers and research workers alike to reasonable conditions of pay, leisure and freedom of speech; and it is odd that some of the academic fracas of recent years have arisen over the demand of men of science for freedom, not of scientific thought or expression, but in the exercise of those civic functions which Dr. Baker regards as incompatible with the "scientific life". Here is Dr. Baker himself compromising his own 'scientific life' by this counterblast to 'planned economy' by or for a 'progressive class': a case of real self-discipline. One wonders whether the geese who saved Rome ceased to lay.

Dr. Baker rather damages his own generalization by admitting (p. 36) that at certain times "if one person had not made the discoveries, another, nearly as good, would probably have done so", distinguishing science from music in this respect. But if "the genius in science is not a man apart" (p. 37), what becomes of the case for treating him as if he were ?

For his general thesis that the desire for knowledge begins in wonder and curiosity, rather than in the desire for control, which leads to technological invention, there is much to be said. It is an aspect of the general distinction between science and technology, between discovery and invention; and it is not surprising that those who fail to distinguish these should overlook it. Dr. Baker's analogy, already noted, between science and music, between the disinterested quest of truth and the quest of beauty, is well grounded. He might have added the quest of goodness, which like the quest of truth has its technological counterpart in the social sciences, which study how to *be* good, or to *multiply* goodness among men; for this also does not originate in the desire to control evil, or lead to the effort to do so, but rather, as its votaries say, 'to see God' without consequence or corollary. Theories of origin, however, do not prejudge the claim of the disinterested 'seeker after truth', or after beauty or goodness, to freedom of thought and expression. They are only relevant in so far as they help to explain the inability of able technologists, as of some able composers, to recognize the division between disinterested and interested inquiry. Dr. Baker quotes the statement (p. 104) that "nearly all scientific discoveries have proved of practical value", which is a tautology if 'scientific' means 'technological', but untrue if it means anything more. Such statements rather confirm his doubt whether we live in a "particularly scientific age" and his view that "even in subjects which are based on science, the scientific attitude is not absolutely necessary", meaning thereby the disinterested quest of truth. Just so, there are zealous and efficient social reformers who doubt or deny the possibility of "knowing the good" in the sense in which a man of science "knows the truth" in his discoveries.

If Dr. Baker's theory of scientific discovery as a conjunction of genius and occasion is true, every community probably gets its ration of men of exceptional insight. What matters is its method of recognizing them, and the use it makes of them when found. Here all parties seem to be agreed that they are likely to be better treated, and more productive of truth, if public opinion is sufficiently cultured to appreciate what they are doing and to provide for their needs, which are usually modest. It is not the discoverer but the inventor, who needs a palatial laboratory and a highly trained team. The inventor, moreover, usually knows better how to humour the unscientific theories or wishes of the patron or party, progressive or otherwise, who will pay the bill. In the arts it is the same; it is the great decorator who lives in kings' palaces and enhances their style of living; and he is not always a great artist.

It would be unfair to Dr. Baker not to note points in which his own presentation of the "scientific life" might be clarified. His classification of the sciences as basic, intermediate, expanded and eclectic is novel and needs explanation; for he seems to exclude mathematics, and to include psychology in biology—though he admits a "temporary gap" between psychological and physiological studies; he underestimates 'experimental' biology, which is as essential as 'experimental' physics; he includes geographical distribution under biology, though volcanoes are geographically distributed, and animals and plants depend for their diffusion on soils and climate; and he overlooks the 'observational' side of pharmacology, where Sir Henry Wellcome spent large sums fruitfully on the folk-lore and folk-medicine of remoter peoples. His use of well-established terms like 'substance' and 'form' is perplexing; he speaks (p. 95) of the "analytically minded person" as interested "in substance rather than form, in the general rather than the particular"; but perhaps he is one of those persons "untrained even in the elements of logic" who are "usually logical enough for all the purposes of ordinary scientific research" (p. 89).

Dr. Baker has several suggestions for the advancement of science: more Nature reserves, more amateur naturalists, a society "for mutual help between them and the professional scientists"—the original project of the British Association; a journal more suited than NATURE to their needs; museums like those advocated by Flower fifty years ago, and locally realized. Will Dr. Baker take a hand in the museum at Oxford?

But all these enterprises imperil the Cynic seclusion of potential discoverers. Either they must be left to chance-and-genius, like scientific discovery, or somebody must attend to them; and this means planning such applications of science; the maintenance of an "environment in which culture is respected" (p. 139); the "elimination of snobbery"—of homage to political influences, "progressive" or otherwise; and, most important of all, the replacement of one generation of men of science by another, through scientific teaching. "Already the majority of research workers spend a large part of their time in teaching, or in other work in which complete freedom is impossible" (p. 50), and Dr. Baker's planning seems likely to diminish their freedom. It is all very sad; the best we can do is to "keep out of the sunlight" of the Cynic who comes in our way, and encourage the "progressive classes" to do the same.

JOHN L. MYRES.

PHYSIOLOGY OF VISION

Vision

A Study of its Basis. By S. Howard Bartley; with an Historical Perspective, by Edwin G. Boring. Pp. xv+350. (London: Macmillan and Co., Ltd., 1941.) 18*s*. net.

AFTER a period of stagnation, the last twenty years or so have seen a remarkable revival of research into the complex and difficult problems of the fundamental physiology of vision. During this time great advances have been made in our whole conception of the state of adaptation of the eye, in our knowledge of the photochemical and electrical changes which take place in the retina and optic tract in response to stimulation by light, as well as of the correlations between different types of stimulus and the sensations produced. There has lately been an urgent need for a book, possibly on the lines of the "Recent Advances" series, which would make the results of modern research more generally available, and would, perhaps, show how such apparently separated subjects as, for example, the photochemistry of the retina and the study of visual sensation under different conditions can be brought together to build up a coherent picture of our present ideas about the processes whereby light, falling on the eye, produces the complicated visual sensations of which we are conscious.

No one who has tried to produce for students a clear picture of our modern outlook on visual mechanisms can fail to welcome Bartley's book. The author has very decided views on the way in which the problems of vision should be approached, and, because his book reflects them so strongly, he is likely to meet with a good deal of disapproval from many, if not most, experts in the subject. Bartley believes, if I read him rightly, that work on vision should approach the subject through the study of sensation rather than via the chemical and other reactions of the retina. He points out, quite rightly, that the final results of stimulation of the eye depend on the characteristics of the whole optic pathway, from the end-organs in the retina to the visual cortex, and that explanations of visual phenomena based on the behaviour of visual purple and the rods and cones of the retina, such as those produced by Hecht, are bound to be misleading. The author's insistence on the inadequacy of this point of view is timely and necessary; but, unfortunately, he has gone too far in the other direction and has, in consequence, produced a book which is, itself, both misleading and one-sided. This is a great pity since he undoubtedly spoils the force of a valuable argument by minimizing, and often altogether ignoring, much important work.

It is certainly true that the Duplicity Theory—which associates day-vision with the retinal cones and night-vision with the rods and visual purple—no longer provides a sufficient explanation of all the phenomena, but this does not detract from the importance and validity of the facts on which the theory was originally based, as well as of recent results which support it. Completely to ignore this body of knowledge, as the author does, in a discussion of dark-adaptation, for example, cannot, to put it mildly, really help in the clarification of the problem. Any consideration of the problem of vision as a whole must include the question of how light is able to initiate nerve impulses as well as how these impulses give rise to conscious sensations. Light energy must act through the medium of photochemical substances, and to ignore all that is known of at least one such substance in the retina is surely odd in a book the title of which is "Vision: a Study of its Basis".

The greater part of the book deals with recent work, much of it the author's own, on sensation. The chapter on the visual perception of movement is particularly valuable, both for its description of experimental work and for its theoretical discussion. There is also a very interesting discussion of the dependence of visual acuity on changes in illumination. The author points out the difficulties in the way of reconciling present-day theories of the effects of raising the illumination on interaction between different parts of the retina with the fact that increased illumination undoubtedly also increases visual acuity. In this connexion, it is a pity that he seems to be unaware of Polyak's recent work on the micro-anatomy of the primate retina, because this worker's demonstration that only some of the retinal cones bear a one-to-one relationship to their optic nerve fibres should help to elucidate this particular problem.

It is good to find, at last, a comprehensive account of the work on the electrical changes in the retina and optic nerve in response to light. Great advances have been made in this subject recently and results of considerable interest, not only from the point of view of vision but also of sensation in general, have been obtained; and Bartley's account is, on the whole, a clear and full one. One cannot, however, help but deplore the fact that his suspicion of photochemical explanations of retinal activity should have led him to omit any reference to the formidable body of evidence produced by Granit and his colleagues to associate the *b* wave of the electroretinogram with the presence or absence of visual purple. In this section, also, very much less than justice is done to Hartline's truly exquisite work on the electrical responses of single optic nerve fibres—work which has been of so much value in helping us to understand the reactions of this nerve as a whole to stimulation.

It is probably true that attention has lately been too exclusively directed towards the retinal end of what might be called the visual chain, and that the author's contention that we can now learn more about vision by studying the physiological psychology of visual sensation rather than the details of retinal activity should, therefore, be seriously considered. Those who wish to learn more about recent developments on these lines will certainly find his book extremely useful and satisfying.

KATHARINE TANSLEY.

INDIAN FOREST UTILIZATION

Manual of Indian Forest Utilization

By H. Trotter. Pp. x+419+18 plates. (London: Oxford University Press, 1940.) 30*s.* net.

THE embarrassing richness of well-forested tropical countries is in itself a handicap to the economic utilization of their timber resources. It is no easy task to select from some hundreds of different timbers those which are most suitable for each particular purpose; instead, the usual practice has been to concentrate on a small number of primary hardwoods which have been found by experience to be durable and generally suitable for everyday needs. This works very well so long as these timbers are plentiful and cheap, but there comes a time when the demand overtakes the supply, prices soar, and it becomes necessary to turn to the lesser-known woods which make up the bulk of the country's forest resources. This was roughly the position in India twenty-five years ago. The timbers most in demand for ordinary purposes were about a dozen in number, among which teak (*Tectona grandis*), sal (*Shorea robusta*), and deodar (*Cedrus deodara*) were pre-eminent. Shortly before 1914, the inevitable began to happen; as a result of the World War, the demand for timber rose with alarming rapidity and the study of the secondary timbers of India was taken up in earnest.

The present War finds other parts of the Empire in somewhat the same position as India was twenty-five years ago; in some cases their state is worse, because of the quantities of Baltic and North American softwoods which they have been importing while their local timber supplies remain undeveloped. Without necessarily taking Indian practice as a model, these countries may still learn much from India in forest utilization.

In the volume under review, the important question of replacing the relatively scarce standard timbers of India by others in more plentiful supply is tackled in commendably practical fashion. The principal uses of wood are dealt with in turn and the chief requirements of a timber for each particular purpose are clearly stated. Timbers for bridge-building, to take a simple example, require to be strong and durable. A descriptive list of representative timbers suitable for this purpose is followed by a table of relative strength values, as a guide to anyone seeking the best structural timber in his particular district. Under the heading of vehicle construction the essential characteristics of timbers for the framework, axles, hubs, spokes, felloes, etc., are set out, and suitable species are recommended for each part. The manufacture of matches is an example of a highly developed timber-using industry which is very exacting in its demands. Strange though it may seem, there are very few woods really good for making match splints and match boxes. Analysis of the requisite properties, however, shows how strict is the specification for a timber which will compare with imported aspen, the match wood *par excellence*.

The way in which standards of quality are determined by the materials available is strikingly illustrated in the case of joinery timbers. The outstanding characteristics of an acceptable timber in this class are that it should be cheap, plentiful and not too hard to work. In Europe and North America, the so-called softwoods (pine, spruce, fir, and other coniferous woods) have long since taken the place of oak for three quarters of the joinery work. In the greater part of India, however, conifers are not easily available and the joiner is accustomed to use hardwoods, some of them so hard that they would be regarded with horror by his opposite number in Europe. The greater labour in working hardwoods is offset by their superior strength and lasting qualities, which render them more suitable than softwoods for work of a permanent nature, especially in the tropics. It is unfortunate that the prejudice in favour of softwoods has spread from Europe to many parts of the tropics before local timber resources have been developed sufficiently to hold their own. The imported softwood has the advantage that it is well sawn and seasoned ready for use—an important consideration to the contractor; on the other hand, it is not very resistant to the fungus and insect pests which attack timber in tropical climates. In every forested tropical country there are indigenous hardwoods which are known to be superior to softwood, and it should only be a matter of time before they replace the imported material. It is essentially a matter of organizing local resources.

The chapter on the uses of wood from which examples have been taken is an admirable summary of the technical data on individual timbers accumulated in the records of the Forest Research Institute, Dehra Dun. The other chapters dealing specifically with timber cover the structure and properties of wood, felling and conversion, transport, storage, and the important auxiliary industries of seasoning, preservation and wood-working.

A substantial portion of the book is devoted to the so-called minor forest products which are of such enormous economic value to India. Some of these are the basis of important industries: lac, turpentine and rosin, charcoal, and paper pulp, for example, are each given a separate chapter. Others are conveniently classified under half a dozen headings as fibres and flosses, drugs and spices, oilseeds, distillation products, tans and dyes, etc. Many of these commodities are the subject of monographs, but so far as I am aware, there is no single volume readily available which covers the whole field. This part of the book, therefore, will be of particular interest to anyone seeking a brief elementary account.

Of the book as a whole it may be said that the author has given the reader what he wants to know in a form in which he can easily utilize it. The preface states that it is intended primarily as a text-book for Indian forest ranger students, but there can be no doubt that it will also be welcomed by senior officers of the Indian Forest Service and will be found useful for reference by a wider circle of readers. It is only to be regretted that the author has not seen fit to include at least a short bibliography of forest department publications and other more exhaustive works which the reader may wish to consult for fuller details.

B. J. RENDLE.

EDUCATION AFTER THE WAR

By M. L. JACKS

Director of the Department of Education, University of Oxford

THERE are to-day signs of intense activity on the whole educational front, and local advances are being planned and discussed and sometimes put into execution on many sectors. This movement is to be warmly welcomed, but it has in it certain dangers: of these the chief is that it is largely an unco-ordinated movement. This may be inevitable at the present stage of development, but it is a feature in the situation which should be brought to an end at the earliest possible moment. Until the campaign can be seen as a whole and a proper strategy worked out for carrying it to a successful conclusion, there is a grave risk of our frittering away our forces in tactical advances which are of no ultimate value, in concentrating our strength at one point and weakening it at another equally vital, and in occupying positions which are only tenable (and indeed only worth holding) if an advance is made along the whole line. It is to this advance of the whole line towards a comprehensive objective that we must devote our attention. *Quo vadimus?* In this article I shall endeavour to set up three direction posts and to indicate briefly to what they point. To drop the metaphor, I shall suggest three general principles which should guide our planning of post-war education, and apply them to certain practical problems.

My first principle is the principle of *wholeness*—the wholeness of the child, and the wholeness of his educational experience. Education viewed from this angle might be described, on the analogy of total war, as *total education*, and those who care to work out the analogy will find in it much that is suggestive and helpful. It has not been our custom in the past to educate our children as integrated wholes: our tendency has been rather to analyse them into wholly artificial parts, and then to try to educate these in isolation from one another. Thus we have adopted a tripartite division into body, mind and character, which has become traditional: the body we have educated (or rather exercised—by no means the same thing) on the playing-field, the mind in the class-room (and for many this has comprised the whole of education), and the character in the give-and-take of school life; there has been little deliberate effort to educate the will or the emotions. The result has been that not only have we failed to educate the whole man and have turned out from our schools those unbalanced personalities which are such a danger both to themselves and to their fellows, but we have also not even succeeded in educating any one of the three parts; for the truth is that we cannot educate one unless at the same time we educate all the rest. "A teacher comes to grief", says Prof. Whitehead, "as soon as he forgets that his pupils have bodies."

Education, if it is to be effective, must always mean the co-education of all parts of the human personality. To take a particular illustration, physical education can never be an end in itself or limited in its objective to the body; to demand this, and to make a meaningless 'physical fitness' our end, is self-defeating. Physical education means the education of the whole man through his body, a truth of which Plato was aware when he said that "Gymnastic" was primarily for the soul. To act on this principle of wholeness will clearly mean considerable changes in our choice of subjects and in our methods of teaching them; we shall have to make a deliberate attempt at synthesis in constructing our time-tables and in organizing our school-life, so that a day at school may become a piece of intelligible tapestry instead of the patchwork quilt which it so often is. We shall have to change our very conception of a 'subject', and perhaps give up the use of the term (and a good riddance), substituting for it the conception of an activity, and the activity of a whole human being. This human being, moreover, is a whole *now*, and there is a wholly right life for him to live to-day; to provide that life is to educate him: education is not a preparation for something else, for a distant and uncertain future, for earning a living or citizenship or life, but is a whole life (and a different life) to be lived by each child here and now; out of that life the right future will develop as the flower from the bud.

Moreover, the process must cover the whole period of childhood and adolescence; up to the age of eighteen (at least) the boy must be subject to educational authority, and if he leaves school for part-time employment in a factory at fifteen or sixteen it must be because it is there that his education can best be carried on. This is very different from the continuation school plan, under which a controlling industry will let off an employee for so many hours a week to continue his education. Industry can play its part by friendly co-operation with the school, by stressing the educative side of its young employees' work, and perhaps by the establishment of works' schools. Such an educational scheme implies a social revolution; but education and society are so closely interwoven that the revolution which we all see to be necessary in one cannot be carried out without a parallel revolution in the other.

So much for wholeness. My second principle is that of *comprehensiveness*. The connotation of the word 'education' has immensely widened since the days when it stood for little more than the three R's, and it is widening every day. We now know that education means much more than teaching even a vastly increased range of subjects; it means the provision of everything a child needs for the discovery and full development of all his potentialities—physical, intellectual, emotional, moral and spiritual. Nutrition and health, milk and meals, rest and sleep, cleanliness and clothing, the encouragement of aptitude and creative skills, the growth of emotions into valuable sentiments, training of the æsthetic sense and of social attitudes, vocational guidance; all these are properly part and parcel of the educational process for *all* boys and girls, and not only for those who, by reason of home circumstances, seem to stand particularly in need of them; it is very often those who seem to need them least who do in fact need them most, and none of these elements in the educational process must be tarred with the brush of State-charity.

There must be, moreover, a new marriage between the cultural and the technical, and that false and unfortunate dichotomy must be ended in a new conception of twentieth-century culture. The old dividing line between a 'liberal' and a 'vocational' education (never a very clear one) must be erased wherever possible, and we must so teach our more specifically cultural subjects that their vital relationship with the technical may be recognized, and so teach our more specifically technical subjects that their full cultural possibilities may be realized. The curriculum, moreover, must be widened. There has been a rapid movement in this direction during the past thirty years, a movement to which evacuation experiences have given an added drive; many schoolmasters, evacuated to a new environment and compelled by the exigencies of war to devote the time of their pupils to activities which have never hitherto fallen within their purview, have found, to their surprise, that these activities are often more educational than the class-room subjects whose time they have usurped. It is to be hoped that this lesson of evacuation will never be forgotten. But a wider curriculum can only be maintained if it is accompanied by greater freedom of choice on the part of the boys and girls for whom it is provided. We need a much greater variety in post-primary education, whether this takes the form of a greater variety of schools or a greater variety of 'sides' within the same school. I can visualize a post-primary education in the future of which the staple constituent will be book-learning as in the secondary school with which we are familiar, and at the other end of the scale an education in which book-learning will be almost non-existent, with infinite gradations in between: I visualize schools which are more like clubs, new types of boarding-schools (on the lines of the present camp-schools), schools which are day schools up to a certain age and boarding-schools beyond that, and many other varieties. Only in such a variegated field shall we be able to attain that 'equality of opportunity' in education which is to-day a popular slogan, but like most slogans very ill-thought out. It does not mean equality of opportunity to attend a certain type of school enjoying a fictitious prestige, or equality of opportunity to go to the university. It means that every child should enjoy an equal opportunity with every other child to receive *the right education for him*, and that means that we must have available types of education to meet the needs, intellectual, moral, physical, and spiritual, of all children.

My third and final principle is that, in a far more real sense than ever before, *the schools should serve the community, and the community the schools.* The community demands that the product of education should be the good citizen; the individual demands the development of a unique personality. These demands are often regarded as contradictory; they are in fact complementary, for the fully developed individual is the life-blood of democracy, and the best citizen is the man who has been given the opportunity, and has taken it, to become his best self. This truth is more likely to be appreciated, and the duty of the community to the school and of the school to the community is more likely to be performed, if there is a much closer association between the two. On one hand there should be no schools outside the national system. This does not mean standardization, or the reduction of all schools to the dead level of the few categories which we know; for the national system itself is capable of expansion to embrace a much wider variety of schools than it does to-day, and there should be room within it for all those diversities of educational life and experiment represented by schools which are at present independent of public support: given public support, they must, of course, be open to all who can profit by the education they offer, and our ideal should be schools common to all classes but diversified in type.

The two essential freedoms to safeguard are the freedom of the parent to choose his child's school, and the freedom of the school to choose its pupils, both freedoms being exercised within wide limitations. This association between school and community can be further fostered by the encouragement within the school itself of realistic social studies. I do not mean by this courses in civics or current affairs, though these may have their importance. But citizenship is best learnt by practising it within the school community, and its significance can best be appreciated by the study and use of the community immediately outside the school walls. The locality should, in fact, be the first text-book of every school. If that can be done, there will be less danger of that community-sense which many of our schools foster (and particularly our boarding-schools) stopping short, as it so often does, at a school-community-sense, and a bridge will be built (one of the most difficult bridges to build) between school and 'real life'. That should be the beginning of an outward movement which will end in the world-community claiming the allegiance of the world-citizen.

Finally, the 'walls of partition' must be broken down from the outside as well as from the inside, and if the school is to go out to the community, the community must come into the school. To some extent this is being done, and it is symbolical of the change that, whereas in the nineteenth century schools were surrounded by high walls and locked gates, to-day they are commonly built open to the streets and the gates are rarely shut. But the flow of traffic through this open gate is not yet as free as it should be. There is no reason why the industry and the craftsmanship of the neighbourhood should not find their way into the classroom and display their wares and expound their ways of life there—invaluable recruits to the teaching profession; there is no reason why other recruits should not be found among representatives of the local authority and of the professions; there is no reason why the schools themselves should not become community-centres for education, providing classes and courses and cultural activities for children in the day-time and for their parents in the evenings. In these ways social studies would become a real and vital element in the curriculum, and the association between school and community would be complete.

Much has necessarily been left unsaid in this article. No mention has been made of the universities or of adult education: the whole field of religious education has been left unexplored—if explored, it would be found to affect profoundly not only the curriculum, but also the whole organization and administration of the school; and nothing has been said about the training of teachers or the relationship between teaching and other forms of youth service. But I hope I have succeeded in erecting certain pointers to the education of to-morrow.

STRUCTURE AND ROTATION OF GALAXIES

A SUCCESSFUL and well-attended symposium on the structure and rotation of our own Milky Way system and of external galaxies was held at the rooms of the Royal Astronomical Society in Burlington House on July 10.

The discussion opened with a contribution by Dr. A. Hunter on interstellar absorption and the scale of the Galaxy. Pointing out that the absorption produced by interstellar matter is important in studies of galactic structure because of the effect which it may have on estimates of stellar distance, Dr. Hunter went on to review modern methods of determining great distances in astronomy. Except within about a hundred light-years of the sun, the distance of a star is found by comparing its apparent brightness with its true brightness, this latter being estimated by physical examination of the star's light. The distance then follows by applying the inverse-square law. If this law does not hold, however—if, for example, we attribute wholly to the effect of distance dimming which is partly due to absorption—we shall over-estimate distances by amounts which may be very serious if the absorption is heavy. In the past decade many attempts have been made to determine the absorption in various directions. Nearly all depend on comparing photometric distances of distant objects determined as outlined above with distances inferred by geometrical means. Trumpler, for example, arguing that the diameters of physically similar clusters ought to appear smaller in proportion to their distance, found that distances so estimated could only be reconciled with photometric distances by assuming an average absorption of 0·67 stellar magnitudes for every thousand parsecs.

Other work on broadly similar lines has more recently led to much the same result for observations made close to the galactic equator. Hubble's results on the dimming of extra-galactic nebulæ by absorption in our own system suggest that the obscuring matter is confined to a thin layer fairly close to the galactic plane. Meanwhile, spectroscopic observations of interstellar reddening in the light of distant objects of all kinds have been made by photographic and photo-electric means. Coefficients of this selective absorption depend greatly on galactic latitude and longitude, the reddening being greatest at low latitudes and towards the galactic centre. The correlation with distance is very rough, but the value of the mean coefficient taken around the galactic circle suggests that only about one third of the total absorption is selective. Our present picture of absorbing matter in the Galaxy is one of irregular clouds close to the plane of the Milky Way superposed on a thin stratum which dims the light of stars in and behind it according to a cosecant law down to a galactic latitude of 10° or so. Less than half this absorption is selective, the reddening caused by this part being due to particles scattering according to a λ^{-1} law; the rest is non-selective blocking, presumably by larger particles. The stratum extends to at least 2,000 parsecs from the sun, but we cannot say that it necessarily permeates the Galaxy: it may be (to this extent) local. The irregular obscuring clouds closer to the plane of the Galaxy produce heavy absorption and reddening. The recognition of this absorption during the last decade has roughly halved our estimate of the size of the Galaxy and thus incidentally brought it more nearly into accord with that of other giant systems.

Dr. H. Brück, in a contribution on the structure of the Galaxy with special reference to the neighbourhood of the sun, took up the question of the interpretation of star-counts made up to distances of about 2,000 parsecs from the sun. The density function derived from these data, assuming the form of the luminosity function (which is fairly well known), depends greatly on the value assumed for the interstellar absorption. Away from the galactic plane the absorption is small and interpretation is not difficult, but close to the galactic equator the analysis becomes less and less easy. If the absorption is assumed negligible, the well-known Kapteyn universe results, with the sun central in a universe of stars the density of which falls to 10 per cent of its central value at 500 parsecs along the axis of symmetry of the Galaxy and at 3,000 parsecs in its plane. Charlier's "local cluster" of *B* stars, with the sun eccentrically located 70 parsecs from the centre of a flattened system 700 parsecs in diameter and 250 parsecs thick, is now regarded as only the nucleus of a much larger cluster associated with Gould's belt. This cluster may itself be one of many star clouds which constitute the Galaxy as a whole; certainly the observations of galactic rotation prove conclusively that the sun is located at least 8,000 parsecs from the galactic centre. The steep negative density gradients of Kapteyn's universe cannot be eliminated by the assumption of a constant coefficient of absorption: if the absorption postulated is big enough to give constant space densities out to 1,000 parsecs, then rapid rises which are quite unlikely set in farther out.

The compromise due to Bok, who uses a coefficient of 0·4 mag./kpc., yields a density distribution which is roughly constant up to 1,000 parsecs in directions perpendicular to that of the galactic centre, which decreases rapidly towards the anticentre, and which first decreases (100–800 parsecs) and then rises again towards the centre. This tentative picture of a local system elongated at right angles to the direction of the galactic centre tempts us to believe that the sun is situated in a spiral arm of the Galaxy; but Oort's work leads to a very different conclusion. This is based on observations of stars of the 10th to 17th magnitude in galactic latitudes higher than 10°, and is thus independent of the worst irregularities due to absorbing clouds nearer the equatorial plane. On the basic assumption that all absorption has occurred before the mean distance of the 10th magnitude stars, Oort finds that the sun is in a region of low density surrounded in all galactic longitudes by higher densities. The suggestion here is that of a 'local void' between two spiral arms rather than a local cluster, and discrimination between the two hypotheses must await further observations.

Sir Arthur Eddington then gave an account of our present knowledge of the rotation of the Milky Way. The effect of galactic rotation is observable both in the radial velocities and in the proper motions of the stars, but the data from which its amount is determined are in fact confined to the radial velocities, the proper motions providing only confirmatory evidence. In the neighbourhood of the sun, the planetary-type motion distorts a cube of stars into a rhomboid by an action analogous to a shear; differential motion is then observed between the faces of the cube, and terms of the form $Ar \sin 2(l-l_0)$ are necessary to represent the observations. The rotational constant A is about 17 km./sec. per kiloparsec. The actual rotational velocity in the neighbourhood of the sun is obtained from radial velocities of distant clusters: it amounts to 250 km./sec., the distance to the centre of rotation being 10,000 parsecs (this agrees well with Shapley's figure when interstellar absorption is taken into account), and the total galactic mass being roughly 10^{11} times that of the sun. The time of one complete rotation is about 250×10^6 years, a figure which has remained unmodified since the pioneer work of Lindblad and Oort.

The observations of galactic rotation throw some light on the question of the reality of the local cluster discussed by Dr. Brück. Rotational shear in such a cluster would be expected to spread it into a ring—certainly a cluster having the shape of a flattened ellipsoid of revolution would be unstable in a rotating galaxy. This objection is quite independent of theory: it is an observational fact that shear exists in the neighbourhood of the sun, hence that any local cluster must be at best a transitory phenomenon. This view is supported by observations of the cosmic cloud. The interstellar atoms and molecules responsible for stationary lines in stellar spectra are widely distributed throughout the Galaxy and show the same galactic rotation effect as the mean of the stars. It can be shown that these interstellar particles must move with velocities corresponding to circular orbits, otherwise impossibly large density gradients would be set up; hence the stars, too, are so moving, and any local cluster could not persist. From this point of view Sir Arthur welcomed Oort's hypothesis as a way of avoiding the dynamically unstable singularities involved in the hypothesis of a local cluster.

The discussion was wound up by the Astronomer Royal, Dr. H. Spencer Jones, who took as his subject the rotation of extra-galactic nebulæ and their internal distribution of mass. Pointing out that the planetary-type rotation described for our own Galaxy by Sir Arthur Eddington referred only to the solar neighbourhood, presumably at about 10,000 parsecs from the centre, Dr. Spencer Jones turned to spectroscopic observations of the rotation of other galaxies. These referred until recently only to the bright central portions of such objects as *NGC* 4594 and 4111, the rotation of the nuclear regions of which is of the 'solid' type giving constant angular velocities.

Within the last few years, however, work at the Lick Observatory has made available rotational velocities for the Andromeda nebula (*M* 31) and *M* 33 out to considerable distances from their centres. The results of Babcock for *M* 31 show a period for the core of 11×10^6 years, and for the main body of 92×10^6 years, and indicate that much of the mass is in the outer regions. In *M* 33 Mayall and Aller find that the velocity increases at first linearly with radial distance from the centre, then faster until at the edge of the main body a maximum velocity is reached corresponding to a rotation period of 59×10^6 years. In the outer parts the velocity decreases again, the corresponding periods varying from 60 to 200×10^6 years. In these regions Oort's rotational "constant" *A* varies from 84 km./sec./kpc. at 1,280 parsecs from the centre to 30 km./sec./kpc. at 1,920 parsecs, a rough extrapolation indicating that at about 2,200 parsecs conditions of rotation similar to those in the solar neighbourhood would be reached. This in turn indicates that if *M* 33 and our own Galaxy are comparable bodies, the sun is at a distance from the centre of at least twice the radius of the main body, and that from an external galaxy the main body would appear only about 8,000 parsecs in diameter, the sun being well beyond this in the thin outer regions. The observed distribution of rotational velocity in both *M* 31 and *M* 33 can be adequately represented by a thin-disk model, possessing circular symmetry, the individual parts of which revolve in circular orbits about the centre in the plane of the disk. Assuming that in such a disk the surface density can be expressed as a fifth-degree polynomial in the distance from the centre, Wyse and Mayall have determined the curves of force and thence of rotational velocity for typical disks. Then by working backwards they deduce the density distribution in *M* 31 and *M* 33 necessary to fit the observed velocity curves.

A wide distribution of mass throughout both systems is indicated, little tendency being found towards the central condensation usually postulated for our own Galaxy. In *M* 31, for example, the model of best fit consists of two concentric thin disks, and indicates that less than 1 per cent of the mass is contained in the central regions. The total mass is $9{\cdot}5 \times 10^{10}$ suns, which agrees well with that of the Galaxy. A rediscussion of Oort's constants of galactic rotation shows that the information they yield concerning the distribution of matter in the Galaxy, while consistent with strong central condensation, does not lead uniquely to such condensation. It may well be, then, that the mass of the Milky Way system resides largely in its outer regions, in which the sun lies. The question then arises, Why should the brightness of a galactic system be so much less in the outer regions than near its nucleus? Can it be that the luminous giant stars occur near the centre while dwarfs tend to preponderate in the outer regions; or is non-luminous dust so widespread round the periphery that it contributes much of the total mass of the Galaxy? These and many other questions of galactic structure must await further observations in happier times.

A. HUNTER.

BRITISH ASSOCIATION CONFERENCE ON MINERAL RESOURCES

THE Conference on Mineral Resources and the Atlantic Charter, held at the London School of Hygiene and Tropical Medicine on July 24–25, was convened by the British Association Division for the Social and International Relations of Science and, like the recent conference on agriculture, owed its origin to suggestions made at the Conference on Science and World Order held last September. The fourth clause of the Atlantic Charter promises equal access on the part of all peoples to the natural resources of the world, and as minerals are among the most important of those resources, it was felt that a survey of the situation might clarify ideas; the general state of information as to the distribution and nature of mineral deposits among the public and even, it is to be feared, in higher quarters, being very imperfect. Coal and oil were excluded from the scope of the discussion as requiring separate treatment. Those who have had occasion to examine questions concerning mineral deposits have been impressed by the unsatisfactory condition of the statistical knowledge about them which is available, in spite of excellent isolated efforts, and for that reason prominence was given to this aspect in the resolution which was put by Sir Stafford Cripps and passed at the end of the Conference. After a preamble referring to the Atlantic Charter, this ran:

"This Conference, having specifically dealt with mineral resources, submits that, as a first step, the Council should initiate forthwith consultations with appropriate scientific and technical organizations, to secure an understanding on the principles involved. The Conference would further urge that a scientific review of mineral resources, using and supplementing all existing data, should be among the first tasks of any international organization for the social applications of science, such as was envisaged at the recent Conference on Science and World Order. To this end, the Conference recommends that the Council should consider how it might help to promote the establishment of an International Resources Organization, as a fact-finding and advisory body for Governments, as a contribution to world stability, and in the spirit of the Atlantic Charter."

The Conference, which was well attended, was opened by the president of the Association, Sir Richard Gregory, who referred briefly to the new industrial revolution brought about some sixty years ago by the introduction of alloy steels, bringing unfamiliar metals into prominence; metals which are most unequally distributed in the crust of the earth, and thus having special significance in the light of the Atlantic Charter. Sir Thomas Holland, whose presidential address at the South African meeting of the Association first directed attention to the international importance of this irregular distribution of economic minerals and its bearing on preparations for war, then took the chair.

As examples of the questions to be considered, Sir Thomas Holland mentioned that the United States, with its vast steel industry, consuming 750,000 tons of manganese ore in 1937, was unable even with the help of a 100 per cent protective tariff to produce from home sources more than 5 per cent of her own requirements. Germany, also lacking manganese. was tempted by the great resources of South Russia in that metal, perhaps more than by petroleum, Great Britain was almost self-sufficient for the few and simple essential constituents of steel until the last quarter of the nineteenth century, but found itself dependent on distant parts of the Empire and on foreign countries for the alloying elements now needed. Unlike some other natural products, metals cannot be made synthetically for industrial use, and although for certain minor purposes they may be replaced by plastics, they remain indispensable to industry. This dependence necessitates the international exchange of minerals, and if this is to be facilitated, as it must be in a peaceable world, the knowledge of their distribution must be both more complete and more widely diffused.

Prof. H. H. Read, after apologizing to the many geologists present for his elementary treatment of the subject, gave a lucid account of the geological conditions which determine the distribution of mineral deposits. National boundaries have paid little attention to geological regions, and impossible demands for autarky have been made by dictators ignorant of their countries' geology. An autarky based, like that of the U.S.S.R., on a proper estimation of native resources is one thing, and an autarky based on legislation quite another. Even such a wide grouping as that of the United Nations is not completely self-sufficient in minerals, and still less any single country, however extensive.

It was natural that several of the speakers, who had prepared their papers independently, should select the metals used in the production of alloy steels as typical illustrations of irregular distribution. Prof. C. B. Fawcett, speaking of key metals and the location of industry, pointed out that these exceptional elements, such as tungsten, molybdenum and vanadium, are mainly found in the older rocks and for the most part in thinly populated areas. The quantities required are small in proportion to the tonnage of steel produced, and it is also characteristic of them that they pass entirely into the finished product, the loss in manufacture being almost negligible. Many of them occur in such a form that the ores have to be submitted to some kind of concentration before extraction. They are mainly consumed in the regions where heavy industries of the more advanced type are situated; industries employing much skilled labour. These are usually regions of long-established industry, and the gravitation to them of the key metals tends to confirm the existing location of those industries. A dominant fact is that they are essential to the production of armaments and to the making of tools used in that production, so that under existing political conditions no State can feel secure unless it has within its borders a considerable armaments industry. The importance of recovered or scrap metals, dealt with by later speakers, further tends to anchor the highly developed industries to their existing locations.

Prof. P. G. H. Boswell, dealing with the need for better and more complete statistics, reviewed the available sources of information and referred to the lack of uniformity in the definition of available resources. Much information about known resources and estimated reserves is locked up in the archives of mining companies, and it is a question how far this may be made available. An international commission seems to be the only body which could undertake the work after the War, and a useful beginning could be made even now if finance were provided. Exploration has now covered the greater part of the earth's surface, at least so far as the commoner minerals are concerned, but China still affords a vast field for further exploration, while the search for the rarer elements has been far less thorough.

Prof. Boswell concluded with a warning that the diversion of many geologists during the War to other activities, coming after a period in which the number of men being trained in geology was declining, may lead to a serious situation. British geologists have played a leading part in exploration, and many of the leading geologists of other countries have received their training in Great Britain; the lack of appreciation of the importance of the subject, due to ignorance, calls for the attention of educational authorities. After the War, it may be necessary to provide geologists not only for our own needs, but also for loan to countries where scientific training has been interrupted or destroyed. In the course of the discussion it was suggested that geologists might be attached to legations in the lesser-known countries.

The afternoon session on July 24 was presided over by Sir William Larke, who also emphasized the need for a uniform basis for statistics and the fact that in spite of the British lead in scientific discovery and technical achievement, the nation as a whole lacks appreciation of the value of research. The need for continued inter-allied co-operation in this field and in that of economics was stressed. He alluded to the growing importance of the light metals and to the possibility of extracting aluminium from clay, thus rendering the industry less dependent on the very local distribution of bauxite. The high consumption of power in aluminium production would seem to determine the location of the industry, although for reasons partly economic and partly strategic Germany has built up an important aluminium industry based on electric power generated from brown coal and largely imported bauxite. Like other speakers, he referred to the key nature of the less common metals, large stocks of which had been accumulated by Germany before the War, while no doubt much has been done to conserve those resources by changes in the composition of alloys and in technique.

The remainder of the session was taken up by papers illustrating the general principles by reference to particular metals. Prof. W. R. Jones selected tin, the occurrence of which in useful quantities is confined to a very few regions. The United States consumes 40 per cent of the world's tin, but has not a single tin mine within its borders. Europe provides only 1 per cent of the world's output, this coming mainly from the anciently worked Cornish mines. The alluvial deposits which were the principal source of tin are being rapidly worked out, and we shall in the future be more and more dependent on lode mining. The conditions for the formation of lodes are confined to a few of the older rocks. More efficient concentration of the ores will become important.

Closely allied to the occurrence of tin is that of tungsten, the position of which was outlined by Mr. J. L. F. Vogel. The geological conditions of the deposition of tungsten ores are such that no mining engineer would venture to predict the quantity to be found in a newly discovered deposit. The metal was actually the first to be used in the production of an alloy steel, Mushet having introduced it into his improved tool steel, and it was the main constituent of the high-speed tool steels which attracted so much attention at the Paris Exhibition of 1900. Until 1914 the production of the metal was mainly in Germany, although much of the ore occurs within the British Empire, but since then it has been produced at home.

Manganese ores, which are essential to steel making, were dealt with by Sir Lewis Fermor, who said that whereas manganese is only present in the earth's crust to the extent of 0·10 per cent of the oxide, the ores which are used as its source contain 40 per cent or more of the metal. Of the producers, the U.S.S.R. accounts for well over one-half of the world's supply of almost five million tons, India ranking second. The geographical distribution of this and other economic minerals was illustrated by maps showing the extent of the former continent of Gondwanaland. Ninety per cent of the total production of manganese is consumed in the iron and steel industry, and no satisfactory substitute for it has been found. The paper contained a number of valuable tables, and it was argued, on the basis of statistics of imports and exports, that the Axis countries had no real grievance in respect of supplies of manganese ore. Whereas they produced less than 2 per cent of the total, the pre-war system of international commerce allowed them to secure 26 per cent of the available exports, or 16 per cent of the world's production.

Nickel was discussed by Lieut.-Colonel the Hon. Colin A. Campbell. The greater part of this metal is also consumed in the iron and steel industry, for which it is essential for many purposes, including the stainless steels. Its occurrence is extremely restricted. The first extensive production was from New Caledonia, where it was discovered fifty years ago. The ore, garnierite, is a silicate. The far more extensive deposits of Sudbury, Canada, where the ore is a sulphide associated with copper, were discovered in 1887 and now provide 85 per cent of the total production. The other deposits of the world were reviewed, and even allowing for the opening up of new mines, it seems likely that Canada will account for 80 per cent of the total during our lifetime. The demand is certain to increase as the area of industrially developed countries is widened and their standard of living raised. Its extensive use in armaments gives it high importance in any scheme of sanctions against aggressors.

The last metal dealt with in the session was aluminium, a paper on which was contributed by Mr. M. P. Fogarty. The world output of virgin aluminium was approximately doubled between 1937 and 1941, reaching just under a million tons and it may reach 1,750,000 tons by the end of this year, mainly owing to large extensions in the United States. Secondary aluminium recovered after use is now also an important factor in the industry. The paper dealt largely with the British industry after the War, and contained many statistical data and tables. The utilization of aluminium for civilian purposes has not proceeded so far as might have been expected, but its development is likely to be resumed as soon as the large amount consumed in the aircraft industry is released. An interesting review of new technical methods of utilizing the special qualities of the light alloys was included in the paper.

C. H. DESCH.

(To be continued.)

OBITUARY

Mr. G. C. Lloyd

MR. GEORGE CHRISTOPHER LLOYD, secretary of the Iron and Steel Institute during 1909–33, who died on July 10 at the age of eighty-one, was trained as an engineer, and after completing his apprenticeship spent some years with the Spanish Compañia Transatlantica. He had been at school in Germany, and the knowledge of languages which he gained in his studies and travels was a great asset to him in his later activities.

After a period in a firm of consulting engineers, he joined the staff of the Iron and Steel Institute as assistant to the secretary, but four years later left to become secretary of the Institution of Electrical Engineers. On the death of Mr. Bennett H. Brough he returned to the Iron and Steel Institute, which he served efficiently and devotedly for twenty-four years. Through the foreign meetings of the Institute he made friends among the metallurgists of many countries and was associated as secretary with several international congresses, being a vice-president of the International Association for Testing Materials. His services in this field were recognized by the conferment on him of the Swedish Order of the North Star and of the French Legion of Honour.

In 1915 he was also appointed secretary of the Statistical Bureau of the Iron, Steel and Allied Trades Federation, and for several years was responsible for the collection of statistics and their incorporation into an annual report. In 1918, at the instance of the Advisory Council for Scientific and Industrial Research, he prepared the first edition of a report on the sources and production of iron and other metalliferous ores used in the iron and steel industries of the United Kingdom.

To metallurgists in Great Britain and abroad Mr. Lloyd's knowledge, courtesy and kindliness were well known; to the staff of the Iron and Steel Institute he was a valued friend.

NEWS and VIEWS

Soil-less Cultivation

A review of the recent progress in soil-less cultivation has recently been given by Prof. R. H. Stoughton (*J. Min. Agric.*, 49, 25; 1942). In spite of many misconceptions and difficulties, steady progress has been made both in the laboratory and on small-scale semi-commercial installations, and a stage appears to have been reached when some reliable judgment can be formed on the question. Two types of systems are in use: (1) in which the plants are grown in a tank of nutrient solution with the roots immersed in a liquid medium; (2) where the permanent substratum is an inert material such as sand or gravel, to which nutrient solution is supplied at intervals. Carefully controlled trials have shown that in general the first of these is unsuitable for use in Great Britain, owing to the difficulty of securing adequate aeration for the roots, and the low light intensity. Far more promising results have been obtained with the second method, which may be considered under two main headings, namely, sand and sub-irrigation culture. In sand culture the plants are fed by watering on the nutrient solution from above, the surplus liquid draining away. Tomatoes, chrysanthemums, lettuce and a wide range of vegetables gave very satisfactory crops under these conditions, and promising results have been obtained with carnations using a slightly modified and simplified technique.

The disadvantages of the system, however, are the care needed in the control of the moisture content of the medium, and wastage of materials through drainage, but these are to some extent offset by the small cost of the outlay compared with the sub-irrigation method. In the latter case, the nutrient solution is pumped at intervals from below into the growing-tank until the gravel is flooded to the top, the pump is then shut off and the liquid flows back by gravity to the supply tank. The watering and feeding can thus be made almost automatic, the aeration of the medium is excellent and considerable economy in fertilizer materials is effected. Further, chemical sterilization of the gravel is easily carried out. To meet the criticism that soil-less cultivation results in crops of lower nutritional value, chemical analysis of the carbohydrate, protein, inorganic constituents and vitamin C content were carried out. No significant differences could be established between plants grown in gravel and those grown in soil. Experiments are now in progress at the University of Reading, under a grant from the British Electrical and Allied Industries Research Association, to test, among other things, the effect of heating the solution in the sub-irrigation culture of tomatoes. Work is also proceeding on the chemical testing of the solution by simple colour tests, so that its composition may be readily controlled according to the requirements of the crops.

American Newspaper Reporting of Science News

A review with this title by Hillier Krieghbaum has been published in the *Kansas State College Bulletin* (25, No. 5, Aug. 15, 1941; pp. 1–73); it is the sixteenth in a series of surveys of specialized branches of journalism. The beginnings of newspaper science reporting are traced: there was little interest among the early colonists, but as communities stabilized the outlook of editors grew. Benjamin Franklin could write with authority on science, but more usually items were reprints or grossly misinformed, and coverage was spasmodic. In the 1830's there occurred the rise of the penny Press and stunts and hoaxes became common; but editors were sceptical about the Atlantic cable, and Darwin's theory of evolution was barely mentioned. Again, in 1903, very few newspapers noted the first flight of the Wright Brothers. The section of the American Press led by Hearst and Pulitzer began, at the turn of the century, to search more widely for news sensations, but a fuller appreciation of science as news had to come through the War of 1914–18. E. W. Scripps was a pioneer in encouraging specialist writers for the Press, and it was his *New York Times* that was alone in publishing in 1919 an accurate story on the implications of the confirmation of Einstein's theory of relativity. In 1922 several writers attended the annual meeting of the American Association and one of them received a Pulitzer Prize for his work.

Scripps' interest in science led to the foundation and endowment of Science Service, formally known as the "American Society for the Dissemination of Science", launched in 1921 with the co-operation of three of the national scientific organizations. It was to be composed exclusively of men of science, with a layman journalist as editor; while not intended to be run at a profit, a fair charge for its services was to be made. Trustees were selected from the scientific bodies, the journalistic profession and the Scripps Estate. The first weekly issue of *Science News Bulletin* appeared in April 1921, edited by Dr. E. E. Slosson. To-day it is published for the general public as *Science News Letter*, and for the Press and radio there are syndicated news and features services; the director is Watson Davis, a member of the organization since its foundation. A technique was developed of writing stories for future release from advance information, and these are supplemented by regular articles by specialists. In 1941 the daily newspapers served in the United States reached eight million subscribers, with another million abroad before the present War. Science Service has aimed at being a liaison agency between the scientific world and the general public.

Scientific workers have felt in the past some antagonism—often justifiably—towards newspapermen: the independent scientific journalists of experience realized this and in 1934 formed in the United States the National Association of Science Writers, which now has twenty-eight members. The Association works with organizers of scientific conferences, and usually receives special facilities for advance information and 'off the record' talks. It is a mark of the success of the Association that in 1937 several of its members shared the Pulitzer Prize for reporting. To-day many of the large research laboratories and industrial organizations themselves issue material to the general Press. The 'science column' has become a permanent feature of many of the leading American newspapers, with additional activity in the fields of broadcasting and films, and a high standard of accuracy is maintained.

Early Astronomy in South America

In Leaflet No. 159 (May 1942) of the Astronomical Society of the Pacific, Roscoe F. Sanford gives a brief account of early astronomy in South America. Our knowledge of the subject results from a number of expeditions which were sent from the United States with the object of securing data on various astronomical matters. In 1847 Lieut. J. M. Gilliss, founder of the U.S. Naval Observatory, induced Congress to authorize and finance an expedition to South America to improve the value of the solar parallax. Cerro Santa Lucia in Chile was chosen as the site for the observatory, and great progress was made in the next three years, during which the positions of Mars and Venus were determined simultaneously in Chile and in the United States, mostly at Cambridge. Several years later, the reduction of these observations was carried out and a solar parallax of 8·5″ was derived. Research was conducted in other directions, and eventually the Chilean Government became so interested in the work that it arranged for young Chileans to be taught the use of the instruments. Later it purchased these and founded a National Observatory. Dr. Benjamin Gould, who had carried out the reductions for the solar parallax, interested Sarmiento, the Argentine ambassador to the United States, in a scheme for determining accurate star positions in a zone where observations were lacking, and the result was that the Argentine Government founded El Observatorio Nacional de Argentina in 1870, Gould being chosen as director.

Among other projects in South America, reference is made to another Argentine observatory, built at San Luis, through the influence of Prof. Lewis Boss, director of the Dudley Observatory in Albany, New York. This Observatory obtained a total of 85,000 star positions between 1909 and 1911. Before this, so early as 1890, Prof. S. I. Bailey established a station for the Harvard College Observatory in Arequipa, Peru; this was transferred to South Africa in 1926. In 1903 Prof. W. H. Wright established a station on Cerro San Christobal on the outskirts of Santiago for determining radial velocities. This station was known as the D. O. Mills Expedition of the Lick Observatory, and when the work was completed, the equipment was sold for a nominal price to the Catholic University of Chile. These and other astronomical ventures have established creditable cultural relations and lasting good-will between races with differences in customs, aspirations, and mode of thought, and have led to a better understanding of both scientific and political problems.

Origin of Meteorites

H. H. Mininger, Colorado Museum of Natural History, in a paper entitled "Trends in Meteoritics" (*Sky and Telescope*, 1, 8; June, 1942), gives a short résumé of our knowledge of meteorites. Most hypotheses in the past regarding the origin of these bodies gave more attention to iron than to stone meteorites, and erroneous conclusions were drawn. Chondrules, the most abundant of all meteoric constituents, have almost certainly been formed by repeated collisions between crystals and other solid bodies. For this reason, a situation which would provide for the rounding of crystals into chondrules would also produce the fragmentary matrix in which chondrules are usually embedded. It is suggested that in the past, when the sun was more active, extruded gases crystallized and collected into cometary swarms and within these swarms chondrules were produced by repeated collisions, while the aggregation of the resulting fragments and chondrules gave rise to meteorites. Some of the cometary swarms passed close enough to the sun to allow for the fusing of a percentage of the constituent grains, and this process was carried almost to the point of completely fusing the mass in the Lubbock aerolite, which was described in the *American Mineralogist* (25, 528–33; 1940).

It is surprising to learn that a considerable proportion of stony material which enters our atmosphere is reduced to dust. Dr. Lincoln La Paz has estimated that the Pasamonte meteorite weighed 66,000 tons at least when it entered the atmosphere, but only 4,000 gm. were collected. A huge dust cloud occupying about 1,000 cubic miles accounted for the principal mass of this meteorite. Further research on meteors may well yield useful information on the past history of the solar system.

The Beet Leafhopper

This insect, known scientifically as *Eutettix tenella*, forms the subject of Farmer's Bulletin No. 1886 (1941) of the U.S. Department of Agriculture, by W. C. Cook. We note in this publication a markedly enlarged dimension of its pages as compared with the usual run of its predecessors. Its value is thus enhanced by allowing of larger scale and more detailed illustrations and of a more convenient spacing of the letterpress. The beet leafhopper is native to the western United States and to northern Mexico, and is notorious as the carrier and transmitter of the virus of the destructive curly top disease of sugar beet and also of western yellow blight of tomatoes. During many years past the curly top disease has been a major factor limiting the production of sugar beet in many western areas. The whole problem of its control is a difficult one since direct spraying is rarely of value. In many areas the control of grazing is the most feasible method of attacking many of the plant hosts of this insect. In some cases reduction or elimination of the Russian-thistle, the most important summer host, by mechanical means is possible. The actual status of the natural enemies of the leafhopper is difficult to assess, but they are considered to be of great importance. The most notable are flies of the family Pipunculidæ and parasitic wasps of the Dryinidæ group. Predacious bugs, one of which is *Geocoris pallens*, are said to be of equal importance as parasites in reducing its numbers. The development and successful production of strains of beet resistant to the curly top disease has greatly reduced the losses incurred by the spread of the virus disease. By this means the cultivation of sugar beet has been made possible in districts formerly found to be unsuitable.

Earthquakes Registered in Switzerland

According to bulletins just received concerning earthquakes registered at the observatories of Zurich, Basle, Neuchâtel and Chur, fifteen earthquakes were consistently registered during February 1942 and nine strong earthquakes during March. Many of these have been mentioned previously in the columns of Nature, but epicentres on the European continent can now be given. On February 6 an earthquake recorded at Zurich at 00h. 10m. 46·6s. had its epicentre in the Rheintalgraben to the south of Freiburg. On February 7 an earthquake recorded at Zurich at 03h. 55m. 41·4s. had its epicentre near Venice. This was strongly recorded at all the stations. On February 12 an earthquake registered at Zurich at 16h. 03m. 17·5s. had its epicentre east of the Pelvoux-Massiv, in the Westalpen. This shock also was strongly recorded at all observatories. On February 17 an earthquake with its epicentre between Simmental and Kandertal in the Berneroberland was strongly recorded at all stations, the recording at Zurich being at 11h. 14m. 58·8s. On February 22 an earthquake recorded at Zurich at 22h. 34m. 38·8s. had its epicentre near the Stuttgart Rheintalgraben. The earthquake of February 28 (Zurich, 13h. 49m. 13·4s.) had its epicentre in the Bodenunruhe, and that of March 15 (Neuchâtel, 16h. 06m. 27·8s.) its epicentre to the south-east of the Neuenburgersee.

During April and May, 1942, thirty-one strong earthquakes were registered by the seismographs at the Swiss Observatories of Zurich, Basel, Neuchâtel and Chur, according to bulletins just received from Zurich. One epicentre, not mentioned previously in the columns of NATURE, is for the earthquake of April 12. The shock was recorded at Zurich at 00h. 02m. 53·9 U.T. and apparently came from an epicentre 420 km. distant. This epicentre is most likely to have been in the Udine Province of Italy.

Trachoma in the Argentine

ACCORDING to the April issue of the *Boletin de la Medicina Sanitaria Panamericana*, the provinces of Tucumán, Santiago del Estero, Santa Fé, Entre Rios, Corrientes, Salta, Jujuy and Misiones form the area most seriously affected by trachoma in the Argentine. The school is the centre for the control of the disease in children; specially trained doctors examine the children before school begins, and those found infective are given treatment in dispensaries and are not admitted to school until their eyes are normal. Meanwhile, the patients are visited by public health nurses, who instruct the family in treatment and prevention. Periodic visits to schools and dispensaries are made by medical inspectors of the National Department of Health, and teachers serve as intermediaries between the medical practitioner and the children. Intensive educational work is carried out by posters, leaflets and lectures, and preventive medicines are distributed. The result of this campaign during the last few years has been a reduction of the percentage of children infected with trachoma.

Yellow Fever in the Americas

IN a recent paper (*Bol. Of. San. Panamericana*, **21**, 320; 1942), Dr. Wilbur A. Sawyer, director of the Division of International Health, Rockefeller Foundation, New York, discusses the following features of the yellow fever situation in South America: (1) the absence of a definite outbreak of urban yellow fever transmitted by *A. œgypti*; (2) the absence of yellow fever of any type recognized outside South America; (3) the presence of jungle yellow fever, which takes the form of endemics, or epidemics spread over wide areas of South America. The chief features of control methods consist in weekly inspection of premises for *A. œgypti* larvæ, destruction of breeding-places and search for other mosquitoes by special squads. While cities may be kept free from infection by *A. œgypti* control, vaccination is the only measure practicable against jungle yellow fever; it can be carried out on a large scale and has been found both safe and effective.

Oil-bearing Plants in Sweden

ACCORDING to the June issue of the *Anglo-Swedish Review*, the cultivation of oil-bearing plants in Sweden has developed rapidly. In 1940 the area covered by such plants was only 938 acres, whereas in 1941 it was 21,250 acres, yielding a harvest of 10,000 tons of seed from which 2,700 tons of oil could be produced and 7,000 tons of fodder. This year it is established that the oil plant area is 42,500 or 45,000 acres, out of which 5,000 acres is rape, 32,500 acres white mustard, 1,000 acres poppy seed and 2,500 linseed. The yield will be at least 20,000 tons of seed, from which 6,000 tons of oil can be extracted, representing a little more than one tenth of the normal consumption of margarine in Sweden. It is considered likely that the cultivation of oil plants will be so extended that it will be possible to cover one fourth of the normal requirements of raw material for the manufacture of margarine.

University of London

THE following appointments have been made in the University of London: Dr. F. G. Young, since 1936 a member of the scientific staff of the Medical Research Council, to the University chair of biochemistry tenable at St. Thomas's Hospital Medical School; Mr. B. W. Windeyer, medical officer in charge of the Meyerstein Institute of Radiotherapy, Middlesex Hospital, to the University chair of radiology tenable at Middlesex Hospital Medical School; Dr. Alexander Lawson, lecturer in chemistry at University College, Southampton, to the University readership in organic chemistry tenable at the London (R.F.H.) School of Medicine for Women.

The title of reader in education in the University has been conferred on Mr. J. A. Lauwerys in respect of the post held by him at the Institute of Education.

Announcements

SIR GUY MARSHALL has resigned from the directorship of the Imperial Institute of Entomology. He is succeeded by Dr. S. A. Neave, who has been assistant director since 1913.

SIR LOUIS STERLING has been elected president of the British Institution of Radio Engineers in succession to Dr. C. C. Garrard. The presidential address, which is expected to deal with registration of engineers, will be read before the London Section of the Institution at a meeting to be held at the Federation of British Industries, 21 Tothill Street, Westminster, S.W.1, on September 25.

APPLICATIONS for the conditions of the competition for the Jones-Bateman Cup, offered triennially for original research in fruit culture which has added to our knowledge of cultivation, genetics, or other relative matters, may be had on application to the Secretary, Royal Horticultural Society, Vincent Square, Westminster, London, S.W.1.

ERRATA. "Relationships of some Primitive Tetrapods", by Dr. T. S. Westoll (NATURE, July 25, p. 121): paragraph 2, line 4, for "Burdie-house" read "Burdiehouse"; paragraph 4, line 3, should read ". . . strata of latest Dinantian (Viséan) and Namurian age. . . ."

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

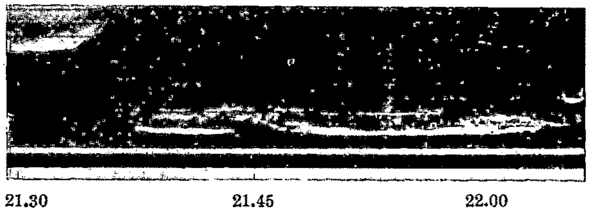
Holes in the Ionosphere and Magnetic Storms

There is good reason to attribute magnetic storms to neutral streams from the sun. These streams have equal numbers of positive and negative ions, because any excess would immediately be dissipated into the surrounding space.

The purpose of the present communication is to suggest, and put upon record, another effect of such streams which is supported by considerable evidence. When a neutral cloud enters the ionosphere, the electrons are brought to a standstill much sooner than the positive ions. Massey and Smith[1] have shown that, at cloud speeds of the order of 10^8 cm./per sec., the percentage energy loss in inelastic collisions for protons, a loss which would reduce their range, is negligible compared with that for electrons, and that the elastic collisions scarcely deviate the proton stream at all. The result is that, under proper conditions, the positive ions in the faster streams penetrate to the E layer, leaving the electrons in the higher regions. There is then a large electric force between the E and the F layers, and this electric force, together with the horizontal component of the earth's magnetic field, produces a violent drift of all the electrified particles in the F layer. The electrons which are in excess, and the positive ions, move from east to west and produce an effective west-to-east current in the upper layer. The opposite movement is produced in the E, or lower layer, but large mass movements are prevented because of the large molecular density there. If the neutral stream is local, the ionosphere is swept fairly clear of negative electrons and positive ions, and a big hole is produced. This may account for the very large reduction in the ionic content of the F layer during magnetic storms. Experiments have indicated that such large reductions do occur, and that these are sometimes much larger than the dilutions which would be produced by the heating of the upper atmosphere, a process which is entirely inadequate to account for the whole effect observed in certain cases. The accompanying illustration is from a photographic record of the 'hole' production during a magnetic storm.

The results obtained by Berkner, Wells and Seaton[2] on ionospheric effects associated with magnetic disturbances show that a hole is produced in the ionosphere at Huancayo at exactly the time that a magnetic storm starts (April 16, 1938). A little later in the progress of the storm, probably when the higher speed particles arrive, a sudden ionization is produced in the E layer. The whole sequence of the events observed at Huancayo can be completely explained in terms of this theory, and the statistical result that practically all magnetic storms are associated with a reduction in the F layer density is also explained.

This hole production is substantiated by a great deal of evidence. The electrons in the F layer and positive ions in the E layer move in such directions as to increase the horizontal magnetic field during a magnetic storm, and this corresponds with the normal first phase of such a storm. It has been suggested that no very marked effect will be produced because the electrons will spiral down the direction of the earth's magnetic field, and recombine at once with the positive ions, but it must be remembered that, as well as this spiral, there is a drift of the electrons from east to west in the upper layer, so that these may be removed far from the positive ions, which drift in the opposite direction before they can recombine. An appreciable increase of the magnetic field will obviously occur. What its amount is depends on the density of electrical particles in the stream. No exact numerical computation of this field increase can be made until this factor is known, but reasonable stream densities give reasonable increases of H. Thus, in a rough calculation, a stream with only 40 ions per c.c. will produce in a few seconds a field of 10 v./cm. with a drift velocity of 10 cm./sec. and an increase in H of the order of $100\ \gamma$.



Height of layer increases from bottom of record.

Although this theory, so far as it is associated with magnetic storms, needs a numerical backing, there can be no doubt about its effect in producing holes in the ionosphere. Much remains to be calculated, and the second phase of the storm may perhaps be associated with the drift of the electrons towards the positive ions, where they recombine. There is, no doubt, a magnetic storm effect as described in the ring production of Prof. S. Chapman. What is the relative importance of these two I do not know. But at least the mass movements of the electrons and their effective magnetic changes should be computed, and a critical analysis made to see if such mass movements can produce the effects observed in magnetic storms.

Biotin, B_1, Riboflavin, Nicotinic Acid, B_6 and Pantothenic Acid as Growth Factors for Insects

We have already stated[1] that biotin is very likely a growth factor for the flour beetle *Tribolium confusum*. Growth of the larva is very much better on a diet consisting of casein, glucose, yeast, cholesterol, salts and water than when yeast is replaced by yeast extract (Table 1, 1). Normal growth is restored by adding the water-insoluble fraction of yeast[2]. All our previously reported experiments indicated that the missing factor in the yeast extract diet was biotin. Since then we have had the opportunity of testing first the most powerful concentrate of biotin then on the market ('Smaco'), and later pure biotin methyl ester ('Smaco'). It was found that both the concentrate (3) and the pure substance (4) improved very strikingly the efficiency of the diet which contained yeast extract instead of yeast.

TABLE 1. Basal diet: 50 parts casein, 50 parts glucose, 1 part cholesterol, 1 part McCollum's salt mixture and 15 parts yeast extract. Twenty larvæ in each test. Temperature 25° C. Relative humidity 70 per cent.

Additions to basal diet.	Period in days during which the first 10 pupæ were formed.
(1) none	39–48
(2) insoluble yeast	28–30
(3) biotin concentrate	28–31
(4) biotin methyl ester	
3·75 γ/gm. dry food	39–48
1·25 ,, ,, ,,	38–42
0·5 ,, ,, ,,	32–40
0·25 ,, ,, ,,	29–36
0·0625 ,, ,, ,,	30–36

The lowest two concentrations of biotin methyl ester used produced about the same effect, which is apparently the optimum. Larger quantities seem to be poisonous. It is, however, just possible that this poisonous effect was due to insufficient removal of the alcohol in which biotin methyl ester was dissolved. Since 0·25 and 0·0625 γ/gm. produced about the same effect, it is likely that the minimum quantities required for optimum effect might be lower still. As has been reported before for rats, yeast and other micro-organisms, the quantities of biotin required are exceedingly small, and many times smaller than those reported for other vitamins.

The availability of most of the members of the vitamin B group in pure substance made possible an attempt to grow Tribolium on a diet in which all the water-soluble B vitamins are supplied in pure form. By leaving out one vitamin at a time it was possible to establish which of the vitamins of the B group are essential growth factors for Tribolium (Table 2).

TABLE 2. Diet: 50 parts casein, 50 parts glucose, 1 part cholesterol, 5 parts insoluble yeast, 1 part wheat germ oil, 1 part McCollum's salt mixture and 15 parts water. Vitamin B_1, riboflavin, nicotinic acid, B_6, pantothenic acid, choline chloride, *p*-amino-benzoic acid (all used at the rate of 50 γ/gm. dry food). Twenty larvæ in each test. Temperature 25° C. Relative humidity 70 per cent.

	Period in days during which the first 10 pupæ were formed.
Whole diet	38–43
Diet without *p*-amino-benzoic acid	36–42
,, without choline chloride	38–43
,, without B_1	40–57
,, without pantothenic acid	50–61
,, without riboflavin	no pupæ; after 105 days most larvæ have died
,, without nicotinic acid	
,, without B_6	
Yeast extract instead of pure vitamins	28–30

From this series it appears that Tribolium does well without choline chloride and *p*-amino-benzoic acid. Without B_1 or pantothenic acid, growth is very considerably slowed down, and without riboflavin, nicotinic acid or B_6 growth comes almost to a standstill. This proves that at least these five vitamins of the B group are necessary growth factors, which is essentially in agreement with recent findings concerning the vitamin requirements of Drosophila[2] and mosquito[3] larvæ. But it does not prove that the two other substances are not necessary, or that the three substances without which no growth occurred are more essential than the two on which slow growth was possible. The diet contained the water-insoluble fraction of yeast, and we do not know what amounts of soluble factors this preparation might still have contained.

It will be noted that growth on the diet containing all the vitamins in a pure state is still considerably slower than when a yeast extract was supplied instead (Table 2). Similarly, a diet which contained the apparently optimum amount of biotin is still noticeably worse than one which contains insoluble yeast instead (Table 1). This indicates that, as was to be expected, there are still other growth factors contained both in the yeast extract and the insoluble yeast.

We wish to express our thanks to the Royal Society for a Government grant which made this investigation possible, to Dr. J. H. Sang for a gift of the biotin concentrate, to Mr. A. L. Bacharach (Glaxo Laboratories) for the gift of samples of vitamin B_6 and pantothenic acid, and to Roche Products, Ltd., for a gift of pantothenic acid.

Steric Promotions and Inhibitions of Polarizations

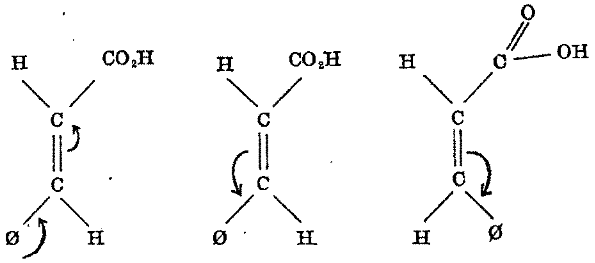
EXCEPTION is taken to the statement[1], "These new results appear to confirm the suggestion made in the Annual Reports for 1939 that the various manifestations of the 'ortho-effect' cannot be interpreted on the basis of a single conception". The *new* results are in complete accord with the ideas expressed in my earlier communication[2]. This letter pointed out that polarizations can be *promoted* as well as inhibited by steric congestion, and the data of R. D. Kleine, F. H. Westheimer and G. W. Wheland[3] offer an excellent example of both.

The dissociation constant of acrylic acid is not much greater than that of trans-cinnamic acid[4], and polarization represented by formula I can be only slightly more developed than that represented by II.

Collision between nucleus and carboxyl group in cis-cinnamic acid produces a torque in the ethylenic linkage which decreases the degree of double bonding; however, this collision occurs at the oxygen atoms and in a direction (perpendicular to the plane of the C-C-O atoms) producing, together with a torque in the ethylenic linkage, an orientation of the carboxyl group (as shown in III) unfavourable to the polarization which develops greater electron density in the neighbourhood of the carboxyl group. In consequence, the polarization shown in III is preferentially developed and the dissociation constant is greater than that of the trans-isomeride. This polarization is augmented by the methyl group in cis-α-methylcinnamic acid and the dissociation constant is correspondingly increased.

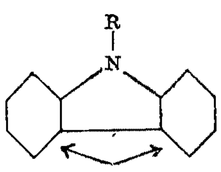
The torque in the ethylenic linkage of trans-α-methylcinnamic acid is produced by the collision of the methyl group with the nucleus, and the weakening of the double bond can be utilized by a suitably oriented carboxyl group (as illustrated by IV) to produce a low dissociation constant. Again, the methyl groups of cis-2 : 4 : 6-trimethylcinnamic acid do *not* orient the carboxyl group out of the plane which includes the carbon atoms embracing the ethylenic linkage; consequently, the dissociation constant of this acid is lower than that of the trans-isomeride.

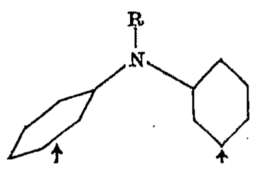
Although the benzene ring has a high reactivity in both *N*-methylindoline and *N*-methyltetrahydroquinoline, only derivatives of the latter can exhibit inhibited mesomerism. For example, one can safely predict that the introduction of a methyl group into the 8-position of the latter will have a depressing effect on the behaviour of the benzene ring towards electrophilic reagents, an effect which will not be realized by the introduction of a methyl group into the corresponding position of the former. Work in these laboratories has shown that whereas 5 : 8-dimethyl-α-tetralone isomerizes to the 5 : 7-isomeride in the presence of aluminium chloride and hydrolyses to γ-(2 : 5-dimethylphenyl) butyric acid with phosphoric acid, 4 : 7-dimethyl-α-hydrindone cannot react in either of these ways. These differences reveal that, in the α-tetralone homologue, ring puckering can allow steric conditions to inhibit the mesomeric effect of the carbonyl group and promote a nuclear polarization represented by V in which the carbonyl carbon atom is deflected out of the plane of the benzene ring.



I II III

Finally, there should be little difficulty in interpreting the lower reactivity (towards deuteration) of carbazole derivatives relative to the corresponding diphenylamine derivatives; only in the latter, as illustrated, can suitable orientation allow of a high reactivity.





The closing of one channel so as to obtain the maximum effect down a second channel was exemplified in my earlier communication[2] by "the abnormally slow alkaline hydrolysis of *o*-relative to *m*- and *p*-acettoluides".

I would like to take this opportunity to express my indebtedness to Prof. J. Kenner for the interest he has taken in the development of these ideas and the encouragement he has always offered me.

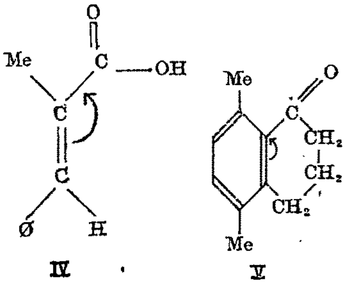
Science, Politics and Service

The contribution of science to the planning of society and particularly to the shaping of its own opportunities seems to be in considerable part confused by a division of many men of science into two contending elements which are essentially parallel with political factions, though perhaps not always conscious of these allegiances.



IV V

A key point at issue is the advisability or inadvisability of State control, that is, whether the works of science are to be centrally organized or left solely to individual initiative, and the gulf between these two views is widened by the opposition of the political impulses of many of their respective adherents. A solution of this *impasse* is obtained by clearly recognizing the need both for organized and for individual development. No one will deny that research in biological and social subjects, and perhaps in others, requires expansion by governmental action and also co-ordinating direction towards the most immediate problems; while the present level of independently undertaken research could be preserved, the work of the limbs of the State-aided scheme could be directed by committees composed of representatives elected by the Government, by scientific societies and by the various research departments, academic and other. Full scope would then be accorded to creative originality, while the nation would also profit from direct contributions by all available experts to its urgent problems; the result would be implementation of common desires, and not loss of freedom. A prime aim of science being to educate and advise, but not to administer, outside its own sphere of working, co-operation with Governments in schemes of research and development would give place for a helpful influence on statesmen.

While many differences in opinion among men of science are a sign of vigour and independence, none the less serious rifts in policy through allegiances to non-scientific causes are likely to be harmful. The growing need for scientists to educate and inform the general public and politicians could not be fulfilled if substantial support had been shown to any one particular faction as a display of personal inclinations, or less personally, to court favours from the apparently more promising source. Politicians are more fickle and self-centred than men of our tradition, it is to be feared and hoped; and also with parties losing or retaining power unpredictably, the financial axe would ever threaten to be used as an excuse to cut down or withhold the schemes urged by the supporters of former Governments or other parties. Expression in active politics seems suitable for the man of science only in his single and private capacity as a citizen; it is not a function of or a benefit to the way of science, and it would enrage just as much as engage attention. The use of the cause of science to give support to the cause of some political party is quite imaginable, though any such confusion, or linkage of causes would be wholly reprehensible.

Men of science, politicians and the various groups of the public largely limit the application of their minds to channels so distinct that their view-points lack sympathetic knowledge each of the others. Unity and power of presentation of policies are therefore essential. Science has often excessively suffered by lack of appreciation of its purposes or by the occasionally misguided zeal of its devotees, and evidence for this misunderstanding need be sought no further than in the sphere of religion.

The duty of men of science is clearly to avoid incrimination of science in party politics but to seek a commonly agreed belief and policy, so far as is humanly possible, for science in general and the sciences in particular, which they would severally labour to enlarge and which they would suitably impress on the non-scientific world with greater force and penetration than are at present employed.

While planning for international collaboration and admiration for the achievements of certain other countries are eminently commendable, the existence of strong elements in Britain, America and elsewhere neither similarly inspired nor likely to be converted by reasoned disquisitions should induce a practical note of not untimely caution. These other countries enjoy great national prides and ambitions, each in its own way; and the British Commonwealth of Nations, realizing that they themselves must play an undeviatingly strenuous part in pressing world peace, will prove their virility and capability for such leadership by assuring their own prosperity, power and honour. Through incomplete understanding of our history, the rallying call of 'Britain and Empire' has become one almost for abuse, though, national prides and sectional urges being what they are and will for long remain, it is essential as a preventive against factious disintegration and as a prerequisite of a still wider well-being. Men of science in the British Commonwealth of Nations should play no small part in fostering all that redounds to the prosperity and glory of Britain and Empire, so helping to draw together the impulses of a great variety of people with advantage for understanding and action in other directions, not the least being appreciation of the full material and social benefits obtainable from science.

Recognition of the beneficial power of our national pride is not shallow nationalism but a reasoned feature of politico-sociology resulting from the observation, as any competent journalist knows, that the great majority of people are reached only through their emotions. Indeed, men of intellectual attainments are in little better straits and their views are very diverse and often antagonistic, so that no reason exists for not seeking and integrating common national traits to serve as a springboard for further progress. Too frequently an active common spirit in the country is promised, somewhat optimistically or alluringly (or even threateningly, as a *sine qua non*), to result only from extensive schemes of reorganization; this spirit of service and fellowship should be engendered now, not only to assist the war effort but also for peace and to prepare for those changes of organization that the country may choose in the course of time. Propaganda—a word denuded of evil if the weight of science and culture were behind it—would here prove of great value for both the present and the future.

It is a tragedy for Great Britain that the valuable qualities of scepticism and individualism among its inhabitants tend to deprive them of the intense love of country and the virility so much needed for strength and progress in these decades when this essentially commercial country is facing both wars and growing competition in the world of industry.

JOHN PETRIE.

Universities in War-time

SURELY the article on "Universities in War-time" in NATURE of July 25, p. 97, omits to mention the most powerful of all motives which impel men to thought and to action at such a time as this and whether they are in a university or in the Fighting Forces; nowhere is 'love of country' or patriotism mentioned. Our lost capacity for moral indignation is lamented; I would rather rejoice over the fact that our sense of patriotism is bright and burning as of old. To mark the fate which meantime has overwhelmed France seems to me to supply an infinitely more powerful incentive to endeavour than the fear of a twilight falling on our "moral standards and spiritual values".

There is another omission of even greater import. Nowhere is it made clear to readers that when a nation passes from a state of peace to one of war, it has to scrap not only its peace-time economics but also, so far as the enemy is concerned, its peace-time code of "moral standards and spiritual values"; to refuse to do so would ensure its speedy defeat. Germany passed from a peace to a war footing in 1933; we are now at the stage which Germany reached about 1936. German universities were bound to the war chariot at an early stage; ours are still free. Long may they be so!

Civilization is defined as "self-discipline", its advance measured "by man's gradual mastery of his more savage instincts". Whether we like it or not, in war we must confront the enemy with the heart of a savage and with a head fortified by all the cunning which civilization can give it. Germans had to give up their individual liberties in 1933; ours have to go now. Will we—or for that matter our enemies—get them back when peace comes? That depends upon what use Germany makes of peace rather than upon our wishes.

An Undescribed Stage of Sarcotaces

THE systematic position of the genus Sarcotaces, according to Calman[1], is quite obscure, for as a result of the extreme degeneration shown by the parasite most of the characteristic features have disappeared. Although *S. arcticus* is not infrequent in the blue ling, *Molva abyssorum*, appearing as dark oval-shaped cysts lying among the myotomes of the lateral line, it has only been very briefly referred to by Collett[2] and Hjort[3], who suggested that it was a Cirripede. Two other species have been recorded, *S. verrucosus* by Olsson (1873)[5] from Acanthurus in the West Indies, and *S. pacificus* from Antennarius at Misaki, Japan, by Komai[4], who suggested that it belonged to the Copepoda.

In all three species the only stages described are the adult female, which occurs in the ovoid cysts of the lateral line and in the case of *S. arcticus* reaches the dimensions of 55 mm. in length by 25 mm. in diameter, and the nauplius, which can usually be found in the space between the female and the cyst wall.

Through the kindness of Dr. R. S. Clark and Prof. Edward Hindle, I have had the opportunity of re-examining cysts of *Sarcotaces arcticus* found in blue ling landed at Aberdeen, and found what seems to be the male form of this parasite.

A total of twenty-six cysts was examined, all of which contained ova and nauplii in addition to the adult female, and in nineteen of them a hitherto undescribed stage was found, shown in Figs. 1 and 2. The numbers present in each cyst varied from one to four; they were always found attached to the cyst wall by their ventral surfaces. Their dimensions never exceeded 3 mm. in length, exclusive of the caudal furca, 0·6 mm, in breadth, and 0·2 mm. in thickness. The anterior part is expanded to form a triangle, ending in a small head (Fig. 2). Slight constrictions seem to indicate segmentation, and there are a number of pairs of vestigial appendages. The head bears four pairs of appendages, antennules, antennæ, mandibles and postoral appendages which may be small maxillules or maxillæ.

The ventral surface of the expanded triangular part of the trunk bears two pairs of biramous appendages, and along the length of the body are one or two pairs of hook-like appendages. The telson bears a caudal furca, which is very variable in size.

The mouth leads directly into the alimentary sac, which like that of the female ends blindly and contains a dense black substance probably derived from the blood pigments of the host. Behind the gut are two masses of densely staining tissue suggesting testes, but the material was not sufficiently well preserved to identify the nature of the cells. Although there was a suggestion of a genital duct leading from these organs, no external aperture could be detected.

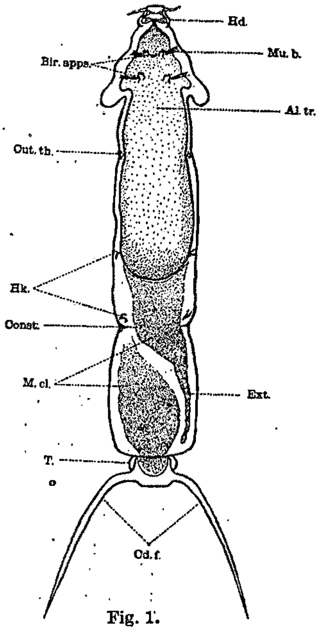

Fig. 1.

Ventral aspect of small parasite from cyst of *S. arcticus*.

Al. tr., alimentary tract; Bir. apps., biramous appendages; Cd. f., caudal furca; Cut. th., cuticular thickenings; Const., constriction of trunk; Hd., "head"; Hk., hooks; M. cl., cell masses (testes?); Mu. b., muscle band; T. telson; Ext., posterior extension of cell mass.

There can be no reasonable doubt that these parasites represent a stage in the life-cycle of Sarcotaces. It is very unlikely that they are the progeny of the large individual, and on the evidence are most likely to be males. Komai claimed to have identified testes as well as ova in large individuals of *S. pacificus*, but this statement is open to question in view of the absence of hermaphroditism in all known Copepods.

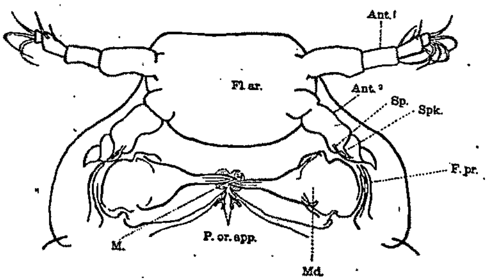

Fig. 2.

Ventral aspect of head.

Ant.^{1}, antennule; Ant.^{2}, antenna; Fl. ar., frontal area; F. pr., falciform process; M., mouth-opening; Md., mandible; P. or. app., postoral appendages; Spk., spike-like process; Sp., spine.

The stage of *S. arcticus* described above suggests that this species belongs to the Copepoda and, in view of its form would seem to be most closely related to the family Philichthyidæ.

Preservation of Historic Machines and Apparatus

Care to ensure that nothing of permanent documentary value should be allowed to go to salvage during the present drive has been publicly emphasized by the Right Hon. Lord Greene, Master of the Rolls, as president of the British Record Association, as well as by other authorities.

The Council of the Newcomen Society directs attention to the corresponding need for watchfulness in the preservation by firms, public bodies and individuals, not only of documents but also of objects of enduring engineering and scientific interest. The Council had before it the case of the irreparable loss to Manchester of Richard Roberts's slide lathe of 1820 which was scrapped because "The lathe was very large and not complete [this was incorrect] and was seriously obstructing our work". A more recent attempt to scrap the contents of Wortley Iron Works near Sheffield, particularly two unique eighteenth-century tilt hammers, has fortunately been averted by prompt action. Such danger of destruction is greatest when the salvagers are enthusiastic but ill-informed persons.

The Council appeals for sufficient delay to get advice when in any doubt; there are several quarters that can give it, which the Society will be pleased to indicate if called upon.

RESEARCH ITEMS

Fraternal Twins

J. W. MacArthur has made an analysis of the factors related to the production of fraternal twins (*J. Hered.*, 33, 87; 1942). He points out that body size of the animals is correlated with the number in the litter. For example, seven generations of mice selected for body size in a plus direction weighed 27 gm. and produced 9–10 in a litter, whereas selected in a minus direction they weighed 14 gm. and produced 5–6 in a litter. Similar evidence is recorded from other animals. Twins are more prevalent among Nordic people than in the Mediterranean region, and the author points out that stature is greater in the more northern parts of Europe. Similarly, Negroes in the United States have a twin rate of 1 in 69 births, whereas the Japanese have the lowest known figure of 1 in 301. Twinning is believed to be inherited through both male and female lines, and to be largely dependent on those genes which influence body size.

Coiling of Chromosomes

Trillium species provide valuable material for observations on chromosome coiling, which is considered by many cytologists to be of fundamental importance. G. B. Wilson and I. Hutcheson (*Canad. J. Res.*, **19**, 383; 1941) show that in *Trillium erectum* reversals in the direction of coiling across the attachment region are at random; across a chiasma there is a frequency of 1 : 6 : 1 of 0, 2 and 4 reversals in direction of coiling of the four chromatids. It is shown that there is an average of two reversals per chiasma. Reversals of direction take place without chiasma formation; once in approximately 17 gyres. There is thus, the authors contend, no grounds for a torsion theory of spiralization and no signs of an inherent ground pattern of structure that determines directions of coiling. A. H. Sparrow, C. L. Huskins and G. B. Wilson (*Canad. J. Res.*, **19**, 323; 1941) have studied the length changes of the meiotic and mitotic chromonemata in *T. erectum* and *T. grandiflorum*. Elongation occurs between early diakinensis and anaphase I and between anaphase II and prophase of the microspore division. Contraction occurs between zygotene and diakinesis, between anaphases I and II and during microspore and prophase. The authors discuss prevailing theories and put forward the view that the coiling is brought about by elongation of the chromomena within a space confined by the pellicle. It is probable that spirals of sister chromatids are always in the form of orthospirals (plectomenic), that is, they are interlocked at each twist. The authors show the importance of this evidence in considering the mechanism of chromosome behaviour.

Pacific Foraminifera

J. A. Cushman now publishes the third part of his work on the Foraminifera of the tropical Pacific collections of the *Albatross*, 1899–1900 (United States National Museum, Bulletin 161; 1942). This deals with the families Heterohelicidæ and Buliminidæ. Certain other related material from shallow water of the same region is also included. Some interesting relationships have been noted in these faunas, in which are living representatives of species known hitherto only from the late Tertiary of other regions. The number of distinctive species in this area is very large. Many were originally described by H. B. Brady from the *Challenger* material. *Bolivinita quadrilatera* is a species occurring in the *Albatross* stations sometimes relatively abundantly, and also in 3–12 fathoms off Fiji. It apparently also occurs in the Atlantic, but it is an interesting fact that the Atlantic specimens as a rule seem to lack the basal spine. The fauna of the Miocene of France is related in many ways to the present Indo-Pacific fauna. It is therefore not surprising that a typical specimen of *Bolivinella margaritacea* described from the Miocene of France should have been found in the material from Rutavu.

Biology of Beetles of the Family Dermestidæ

Memoir 240 (Dec. 1941) of the Cornell University Agricultural Experiment Station is entitled "Studies on the Biology of Four Common Carpet Beetles". Part 1, dealing with three of the species in question, is by Grace H. Griswold, and Part 2, which is concerned with *Anthrenus scrophulariæ* only, is by Margaret Greenwald. It appears that very little detailed work has been done on these important pests. The black carpet beetle (*Attagenus piceus*), the varied carpet beetle (*Anthrenus verbasci*) and the furniture carpet beetle (*Anthrenus vorax*) are widely distributed throughout the world. The larvæ feed upon materials of animal origin and cause much damage to rugs, carpets, upholstered furniture, also woollens, furs, etc. The first two species also feed on cereal products and at times cause trouble in flour mills and granaries. In breeding these insects, woollen cloth of some kind has always been kept in each jar or receptacle and fish meal has proved satisfactory as a food for the larvæ. In all three species several months are spent as larvæ. For *A. piceus* the period was never less than 8 months and some individuals lived as long as 21 months. In the case of *A. verbasci* the larval life was slightly shorter but never less than 7 months, while in the case of *A. vorax* the period ranged from slightly less than 4 months to more than a year. The adult life in the first two species ranged from 13 to 44 days, whereas *A. vorax* lives as an adult from 44 to 251 days, the females living rather longer than the males. The fourth species, *Anthrenus scrophulariæ*, may pass its entire developmental period (egg to adult) in 78 days, but may be prolonged to at least 439 days. The beetle itself feeds upon pollen of various flowering plants—at least twenty-seven species of these being known to be resorted to. The paper includes a list of more than a hundred references to works on the insects in question.

Selachine as a Colour Neurohumour in Sharks

G. H. Parker read a paper on this subject at the annual general meeting of the American Philosophical Society during April 23–25. In the common bull-head, the darkening of the fish is due to intermedine from the pituitary and acetylcholine from dispersing nerve terminals near the colour cells, and the blanching to adrenalin from concentrating nerve terminals also near the colour cells. In the smooth dogfish *Mustelus canis* darkening is due to the pituitary neurohumour intermedine. The occasion of its blanching is less clear. This colour phase has been variously claimed as due to the mere absence of intermedine, to a pituitary blanching agent, the *W*-substance, or to a concentrating nervous neurohumour. No evidence in favour of a *W*-substance has been found in Mustelus, but this fish does blanch on loss of intermedine. When its integumentary nerves are cut the denervated areas become pale. Such blanching is not due to a disturbance in the blood supply, for it occurs when the blood vessels of the region are not interfered with. Such pale areas can be revived by recutting their severed nerves. From such skin a neurohumour can be extracted with ether or oil that will blanch a dark fish locally on injection. This neurohumour is in effect like adrenalin, but it is not adrenalin for it is not soluble in water and it is not destroyed by heat. It is peculiar to the shark; hence it has been called selachine. It causes blanching in Mustelus when the fish is low in its intermedine.

Water Reserves in Brazilian Forest Soils

THIS feature of some of the soil in the vast forest areas of Brazil is emphasized by Felix Rawitscher in his transpiration studies by rapid weighing methods under field conditions (*Anais da Academia Brasileira de Ciencias*, 14 (1), 1942). The soil depth in tropical and sub-tropical regions may reach a maximum of 15–20 metres, and considerable water reserves may be accumulated in the deeper layers of soil. During the dry period of the year these furnish water, not only to sources and streams, but also to the deeper plant roots. Large zones of humid forests in the interior of San Paulo live on these reserves during the dry period. The author suggests that the high transpiration rate of extensive humid forests must have a considerable influence on the humidity of the climate.

Amber Spiders

A. PETRUNKEVITCH's well-known monograph on Carboniferous Arachnida is now supplemented by a lengthy study of spiders preserved in Baltic amber (*Trans. Connect. Acad. Arts. Sci.*, 34, 119; 1942). The 140 specimens named represent 78 species, 69 of which are new, included in 27 families, 5 new. The descriptions are as detailed as the state of preservation allows, aided by a special technique, a full account of which is given. The work is illustrated by more than 500 line figures and 100 photographs. Prof. Petrunkevitch also summarizes the changes that evolution seems to have wrought in the structure of spiders, especially in the circulatory and respiratory systems, leading first to the conclusion that the habits of spiders must have become differentiated before the Oligocene, and secondly to much discussion as to the most acceptable way in which these evolutionary trends may be represented in the classification of the order. The monograph is both informative and provocative to a degree.

High-Pressure Measurements

Two further instalments of P. W. Bridgman's researches on the physical properties of substances at high pressures have been published (*Proc. Amer. Acad. Arts and Sci.*, 74, 399 and 425; 1942). The first deals with freezing parameters and compressions of twenty-one substances, chiefly organic liquids, up to 50,000 kgm./cm.^{2}. The general conclusion from this new work in a pressure range three or four times the previous range is that the melting curves give no evidence for critical point, maximum temperature or temperature asymptote. The curves continue to rise to indefinitely high pressures and temperatures, with continually decreasing slope $d\tau/dp$ and continually decreasing volume discontinuity between solid and liquid. The second paper deals with pressure-volume relations for seventeen elements to pressures of 100,000 kgm./cm.^{2}. In general the compressibility falls off less with rising pressure than might have been expected. Full details are also given of the experimental technique needed to overcome the special difficulties of working at these higher pressures.

The True Galactic Pole

O. R. WALKEY has prepared an account of the various positions found for the galactic pole from the days of Sir William Herschel down to modern times (*Observatory*, No. 808, 64; June 1942). Of the twenty positions determined, seven were derived by the galactic belt, four from star counts, and nine from galactic objects. These are tabulated and are all reduced to the epoch 1900 position. The true position of the galactic north pole, using all the results, is at R.A. 12h. 48m., Dec. + 27°, in Coma Berenices (epoch 1900), and it is remarkable that this coincides exactly with Newcomb's combined position tabulated for the galactic belt. It seems highly probable that the epoch 1950 co-ordinates will be in use after the next meeting of the International Astronomical Union, in which case it will be sufficiently accurate to adopt the 1950 R.A. as 12h. 50m. and Dec. as + 27°.

Solar Eruption and Magnetic Storm of March 1-2, 1942

A PROBABLE connexion between the intense solar eruption of February 28d. 12h. and the magnetic storm which followed has been demonstrated by H. W. Newton (*Observatory*, No. 808, 64, June). M. A. Ellison at Sherborne observed the eruption first on Feb. 28d. 12h. 42m. U.T. in $H\alpha$, and from the presence of descending dark flocculi near the bright emission he inferred that the eruption had been in progress for some time. Observations were also made by P. Laurie with the Greenwich spectrohelioscope, but a cloudy sky prevented observations in the earliest stage of the eruption. While the average duration of a brilliant eruption is about ¾ hour, the eruption of Feb. 28 lasted for more than 3½ hours—an exceptional time; but it is suggested that it may have consisted of multiple eruptions with the greatest integrated intensity between 12h. 0m. and 12h. 47m., and strong evidence for this view is given in the paper. On Feb. 28d. 12h. 0m. there was a sudden fade-out (ionospheric irruption of the Dellinger type) and this continued on some circuits until 20h. This was an abnormal duration for a fade-out of this type. A great magnetic storm commenced 19½ hours after the beginning of this sudden fade-out and the following figures from the Abinger magnetic traces show the intensity of the storm:

D	9° 48·7′ at	1d.	9h.	30m. to	11° 14·8′ at	1d.	7h.	51m.
H	0·18194	1	8	50	0·18706	1	9	59
V	0·43048	2	1	45	0·43224	1	9	59

These are the extreme ranges in each case.

Assuming that the ejection of the stream of corpuscles occurs about the time of peak intensity of the bright eruption, which is also closely indicated by the beginning of the radio fade-out, the time required by the stream to reach the earth was 19·4 hours. The data for Sept. 17–18, 1941, gave 20·5 hours and those for Feb. 28–March 1, 1941, gave 18·5 hours. Statistical evidence suggests that in the case of intense magnetic storms in areas where spectroscopic observations have located a brilliant solar eruption within the preceding 1½ days, the effective time of travel is shorter than the mean.

OPEN-HEARTH FURNACE REFRACTORIES

THE first part of the joint meeting of the Iron and Steel Institute and the Society of Engineers and Metallurgists, held at Sheffield on May 19, was devoted to basic refractories, with particular reference to stabilized and semi-stabilized dolomite; and the second part was confined to a co-operative study of a silica roof trial on a basic open-hearth furnace. The discussion was based on reports and papers already published, to which reference is made in the appropriate footnotes.

Dolomite Refractories

The work described by Dr. J. R. Rait[1] has shown that when dolomite is stabilized, by the use of siliceous materials added before calcination, the principal mineral phases are tricalcium silicate ($3CaO.SiO_2$), periclase (MgO), brownmillerite ($4CaO.Fe_2O_3.Al_2O_3$) and dicalcium silicate ($2CaO.SiO_2$). Insufficient siliceous stabilizer leave some free lime which becomes hydrated and causes disintegration of the clinker, while excess results in the formation of dicalcium silicate ($2CaO.SiO_2$), which may cause 'dusting' at its β–γ inversion temperature (675° C.). If the iron oxide content of the mixture is more than that required to form brownmillerite with the available alumina, dicalcium ferrite ($2CaO.Fe_2O_3$) is also formed, whereas with excess alumina, tricalcium aluminate ($3CaO.Fe_2O_3$) appears.

The stabilization of dolomite by silicate minerals is dependent on the firing temperature as well as the proportions of the reactants. Owing to the limited stability range of $3CaO.SiO_2$ (1,300°–1,900° C.) care is necessary to avoid the formation of dicalcium silicate and free lime in a chemically balanced mixture. This breakdown of tricalcium silicate ($3CaO.SiO_2 \rightarrow 2CaO.SiO_2 + CaO$) may occur in the kiln firing of the clinker or in the firing of the bricks made from the clinker under certain conditions. Small quantities of some materials, for example, $Cr_2O_3.P_2O_5$, suppress the β–γ inversion of dicalcium silicate.

Study of the mineral constituents of stabilized dolomite was effected by X-ray diffraction apparatus, and examination of a number of materials showed that serpentine (used commercially), chromite and chromic oxide all produce clinkers highly resistant to hydration. Zirconia also gave promising results.

The relatively low resistance of fully stabilized dolomite to cracking when subjected to thermal shock is attributed to the physical condition of the material. Cracks, once started, are not stopped or deflected at grain boundaries but are propagated through the grains themselves. Better thermal shock resistance is usually shown by the semi-stabilized dolomite products, which have special spheres of usefulness.

A note by Dr. W. J. Rees[2] indicated that a semi-stable product containing 95 per cent dolomite, 2·5 per cent ball clay and 2·5 per cent mill scale might be used as a crushed aggregate and could be produced in a rotary kiln. The product has a high resistance to corrosion by basic-open-hearth slag and a fair resistance to thermal shock; also its resistance to hydration is such that it can be kept for some weeks without deterioration. It is possible to produce a partially stabilized brick by controlled firing in one operation, but the two-stage method (clinker → brick) is considered preferable as it gives a better shaped brick.

The production of dolomite bricks for use in steelworks was described[3], special attention being given to the replacement of magnesite refractories by stable or semi-stable dolomite bricks.

It has been shown that high-temperature calcination (or even electrical fusion) of dolomite does not yield a stable product. The magnesia and lime formed by the reaction: $CaCO_3.MgCO_3 \rightleftharpoons MgO + CaO + 2CO_2$ are both of moderate crystal size (about 0·5 mm. diameter) but the lime, unlike the magnesia, is readily hydrated after only a few days exposure to the atmosphere. The use of the term 'dead-burned' in connexion with high-fired dolomite is thus a misnomer.

During the last twenty years numerous attempts to stabilize dolomite have been made. Probably the first really successful works-scale experiments were those made in Great Britain in 1934 by Dr. W. H. Tyler and W. J. Rees[4], using a mixture of dolomite and sudanite rock (magnesite + talc). Nowadays, serpentine is used instead of sudanite rock, but the composition of all the fully stable dolomite bricks now in use in Great Britain is essentially the same as that employed in 1934, when dolomite brick technology was greatly advanced.

Apart from serious brick-to-brick variations in the early stages, two serious limitations arise periodically, namely, hydration in storage and 'dusting' in the furnace. X-ray examination showed the former to be due to insufficient silica content or inadequate firing (leaving uncombined lime), and the latter to the formation of dicalcium silicate. It is preferred in manufacture to keep the composition slightly on the silica-rich side of tricalcium silicate and add certain of the known stabilizers (for example, phosphorus pentoxide) to prevent the inversion of the small amount of dicalcium silicate so formed. The high-temperature breakdown of tricalcium silicate can lead to trouble in firing or in subsequent storage of the bricks.

The properties of stabilized dolomite bricks are characterized by porosity and permeability of the same order (20–25 per cent and 0·1 c.g.s. units) as those of magnesite bricks, good volume stability at 1,500° C. and high cold-crushing strength. Their refractoriness-under-load is high, but their thermal shock resistance is rarely greater than two reversals as compared with five to eight reversals for ordinary magnesite bricks. They do not disintegrate on boiling in water for 24 hours and show no free lime by the glycerol or White's test, while their thermal conductivity is little more than half that of magnesite. The analysis, which is determined largely by the silica requirements of the lime to form $3CaO.SiO_2$, shows about 15 per cent of silica and equal proportions of lime and magnesia.

Bricks of the semi-stable type were the first to give successful steelworks furnace service. Although containing free lime, the safe-storage time is sufficient for normal purposes, and better thermal shock resistance is obtained than with the fully stable brick. The storage time can be increased by impregnating the fired brick with organic stabilizers. Semi-stable bricks are usually made by mixing calcined dolomite ('basic') with suitable fluxes, moulding with the addition of a temporary bond such as tar and firing in the normal way.

The porosity is of the same order as that of stabilized bricks but the permeability may be higher.

While the crushing strength is usually adequate, it is often about half that of stabilized brick; but the refractoriness-under-load is fairly high. The thermal shock resistance is definitely superior (twenty reversals or more) and the resistance to slags high in iron oxide and lime is also greater. Chemically, this type of brick differs little from the ordinary 'basic' used for fettling open-hearth furnaces. Silica is slightly higher and the lime content normally exceeds the magnesia content to an extent determined mainly by the composition of the dolomite used.

Promising results, particularly as regards improved thermal shock resistance, have been obtained with mixtures of dolomite and magnesite, but such bricks are not yet manufactured commercially.

Basic Open-Hearth Furnace Roofs

Three factors have contributed largely to improved durability of basic open-hearth furnace roofs in recent years: (1) greater stability of the furnace structure; (2) use of temperature control; (3) slag control. Considerable advances have been made in the last few years as a result of co-operative effort by bodies such as the Open-Hearth Refractories Joint Panel, working under the ægis of the Iron and Steel Industrial Research Council and the council of the British Refractories Research Association.

A fairly complete history of a basic open-hearth silica brick roof[5] has been recorded, from the selection of the raw materials for the making of the bricks to the post-mortem examination of samples from the roof at the close of the furnace campaign.

The principal raw material was Bwlchgwyn quartzite. After initial crushing, dry grinding and mixing with a slurry containing a mineralizer, batch samples were taken for grading control and moisture determinations made. Pneumatic ramming of the bricks and modern drying and firing technique were employed. Specific gravity tests before and after firing indicated that pebbly varieties of the rock inverted to the low specific gravity forms (tridymite and cristobalite) more readily than the normal or non-pebbly Bwlchgwyn rock.

Maintained loads refractoriness-under-load tests at a constant temperature of 1,600° C. were made on the fired bricks. A small expansion at 25 lb./sq. in. and a small subsidence at 50 lb./sq. in. load in a one-hour test showed the suppression of permanent expansion by increased loading and suggested that little, if any, permanent expansion would occur in a roof loaded by its own weight. The permanent expansion of a number of the bricks, determined by heating for 2 hours at 1,500° C., showed good volume stability. Higher values were found for bricks of 2·31 specific gravity than for those of 2·32 specific gravity, although it would appear probable that the tridymite (sp. gr. 2·27) content of the lower specific gravity bricks would exceed that of the others and would tend to revert to cristobalite (sp. gr. 2·32) during the test.

Extensive temperature measurements made by means of rare- and base-metal thermocouples embedded in the roof and a radiation pyrometer permanently sighted on the inside centre of the roof gave a record of temperature fluctuations and temperature gradient throughout the campaign. From the records just prior to gassing the furnace, it was shown that the stack draught was sufficient to draw air through the roof when the stack damper was raised, the temperature near the outer face of the roof falling much more than that in the middle of the brickwork. The hot face of the roof fell from 600° C. to 350° C. in 10 minutes, but not into the range where spalling was likely to occur as a result of the β-α cristobalite inversion, although it was well below the β-α quartz inversion temperature.

The temperature records taken over a complete heat were particularly interesting and showed fluctuations as large as 200° C. during charging of the furnace, but fairly steady conditions during melting and refining. On tapping the furnace, the hot-face temperature rapidly fell 300-400° C. and this chilling appeared with an increased time-delay and diminished amplitude through the roof section towards the cool outer face. At a point 9 in. behind the hot face, the maximum cooling occurred some four hours after the event which initiated it.

Some doubt which has previously existed as to the true significance of temperature readings taken with a radiation pyrometer with flame in the furnace seems to have been clarified, by the observation that when the radiation pyrometer showed a fluctuation of about 50° C. at gas and air reversals, the thermocouple initially ½ in. inside the brick from the hot face recorded a slower fall of about 20° C. It thus appears improbable that the 'flame error' of the radiation pyrometer is more than 10-20° C. and frequent records showing roof surface temperatures in excess of 1,700° C. indicated that this temperature may actually be attained in working without visible damage to the bricks, although the fusion temperature of a seasoned roof has been placed at 1,650° C. The reason for this high-temperature stability of open-hearth roof silica bricks was shown to depend partly on the inhomogeneity of the brick. When a test was made on a portion of brick rendered more homogeneous by crushing to powder, the refractoriness appeared to be some 40° C. lower than before crushing. The high-temperature stability of the continuous cristobalite skeleton is also of undoubted importance, as has been noted in silica bricks from other portions of the furnace containing much greater quantities of ferrous oxide. The temperature gradient through the roof underwent a pronounced change during the first two weeks of the nineteen weeks campaign. The region a short distance behind the hot face became a better thermal conductor as 'seasoning' developed, so minimizing the temperature drop in this part of the brick. It has been further suggested that the size, shape and ordination of the crystals may influence the thermal conductivity so as to produce a change of slope in the temperature gradient near the 1,470° C. isothermal (transition from the grey cristobalite to the black tridymite zone).

Several analyses of the dust in the furnace atmosphere at various stages of the heat wave have shown that, during charging, the dust is mainly iron oxide, lime and dolomite; during melting, chiefly iron oxide and lime with lesser quantities of alumina and silica; and during refining, it consists mainly of lime with smaller proportions of iron oxide, alumina, silica and magnesia. The rate of dust production was highest during charging and least during melting, as might be expected.

The dust in the outgoing gases passes into the regenerators where slagging of the brickwork filling is caused. Analyses of the slagged surfaces of bricks from both air regenerators illustrated this attack.

At the end of the campaign, sample bricks were selected from certain areas of the roof for detailed laboratory examination. Chemical analyses of the various coloured zones generally confirmed the results of previous investigators. Sulphur trioxide and phosphorus pentoxide have not generally been determined in earlier studies, and this work has thrown some light on their occurrence in open-hearth roof bricks. Nearer the hot face, SO_3 was less than 0·2 per cent, but increased suddenly to nearly 0·6 per cent in the reddish cool end of the brick. The concentration of sulphur in this area is believed to have come from the furnace atmosphere, possibly during the making of certain free-cutting steels involving the addition of pyrites to the bath.

Phosphorus pentoxide remained fairly constant throughout the hotter half of the brick and then fell to a mere trace. Nowhere did the P_2O_5.CaO ratio approach that in the slag, nor were the positions of the two maxima coincident. This observation supports the view that the slagging agents in the furnace atmosphere contain but little furnace slag. Small amounts of lead, tin and copper were found in the roof brick, but the volatile zinc oxide was quite absent though abundant in the furnace flues.

Stalactites which formed on the underside of the roof, during the campaign, were found to resemble the hot face of the brick in composition, but the FeO.Fe_2O_3 ratio nearly corresponded with that prevailing in the cooler portions of the black tridymite zone behind. This region of the brick was found to be less refractory than any other.

There was a general decrease of porosity towards the hot end of the roof bricks, which is in accord with the findings of previous investigators. Calculation, however, showed that the weight of absorbed fluxes is insufficient to account for the observed fall in porosity, and it must be assumed that some of the fluid glaze formed on the hot face is itself drawn up into the pores of the brick.

The region between the black tridymite and yellow zones, found in used roof bricks, has been shown to be of very low permeability. Microscopical work has confirmed this observation and indicated the presence of a narrow glassy continuum between the silica grains.

Microscopical examination of thin sections cut from the various zones has confirmed the observations of other workers on the stability of the various silica allotropes. The particular allotropes and their relative abundance in any given area have also been studied by coefficient of expansion curves and X-ray diffraction methods.

The formation of a eutectic between mellorite (a complex lime - ferric oxide - silicate of garnet type) and silica (tridymite or cristobalite) melting at about 1,160° C. was observed and is a factor of importance in determining the life of roof bricks.

It has also been shown that furnace gases can pass through the brick, and sulphur compounds in the gases attack the glassy matrix forming ferric sulphate or ferric oxide, depending on the prevailing temperature.

CAMBRIDGE SCIENTIFIC WORKER AND THE WAR

ALTHOUGH recent surveys of the utilization c science in the War have tended to concentrat upon the situation in industry and in Governmen service, it must be remembered that the universitie are carrying on a considerable volume of war researc in addition to their main function of teaching. critical review of the actual and potential wa function of university research laboratories in Grea Britain would provide a useful addition to presen information, and their position must certainly b considered in any national scheme for the co-ordination of research. It is opportune, therefore, that o July 20 the Cambridge University Branch of th Association of Scientific Workers convened a meetin to discuss these points as they affect Cambridge There was an attendance of more than a hundred and contributions were forthcoming from researc workers in most of the principal departments of th University.

A number of speakers reported on the genera experience of their laboratories, other members o which supplemented their remarks in the discussions. The situation obviously varies considerably fro department to department, but it is clear that som important difficulties are common to all. The mai shortcomings may be summarized as: (1) lack o really important or urgent war problems in som laboratories, and the difficulty of obtaining suc problems; (2) continuance of academic research or more frequently, occupation with 'pseudo' wa research; (3) difficulty of effecting contact wit workers in the same field in Government institution or in industry; (4) hampering effect of secrec regulations, which appear to be sometimes absurdl stringent; (5) lack of organized collaboration including pooling of equipment, between the University departments; (6) difficulty under the presen University regulations of employing Ph.D. researc students on war work, particularly secret work an work carried on by research teams; (7) absence o pooling of scientific teaching with the evacuate universities and colleges in Cambridge (the Cavendis Laboratory is a notable exception).

As was pointed out by the chairman, there ar many scientific workers in Cambridge engaged o secret work of national importance, and their worl could not be discussed at such a meeting. Hence th discussion possibly tended to place emphasis on th less satisfactory aspects of the situation. It is precisely these which most urgently need attention however, and the volume of work represented wa considerable.

The first two points are conveniently considere together. In the field of organic chemistry, fo example, many of the post-graduate research student are working on problems recommended by th Advisory Research Council of the Chemical Society It was stated that the majority of these problem are long-term problems related to the improvemen of the post-war prospects of the chemical industry there is considerable dissatisfaction about this. Man senior members having left to do war-work, a considerable amount of teaching is carried on by th junior members of the laboratory, and it is undesirable to transfer all of them to posts elsewhere The solution lies more in their being provided wit the right sort of problems to solve. The situation i markedly better on the physical or colloid chemical side, where work is being done arising largely out of Service requirements, although some of it is rather long-term in nature. In 'pure' biochemistry it might be argued that there are very few real war problems at all, and this has led to quite a few research workers either continuing with academic research or taking up what might aptly be called a 'pseudo' war problem. It is necessary for biochemists to branch out into the related and more immediately useful fields of nutrition, medicine, bacteriology, agriculture and industrial fermentation. Difficulties here are the sketchy organization of biochemists for war purposes and the generally unco-operative attitude of industry.

The difficulty of meeting or corresponding with colleagues engaged on the same or similar work was instanced by speakers from various laboratories. The official attitude is often one of discouragement or even surprise, and many workers seem to have to rely on chance personal contacts. The stringency of secrecy regulations is sometimes too great, and has the undesirable effect of hampering the progress of work by preventing discussion with other scientific workers attacking similar problems. It is often particularly difficult for university men to obtain the necessary collaboration with industry or with Government laboratories.

The position of Ph.D. students was touched on by several contributors to the discussion. It is necessary to decide whether such persons are students being trained in some specialized branch of science, or whether they should be regarded as scientific workers of adequate experience to carry out successfully certain specific pieces of war work. The general opinion favoured the latter course as being more in line with the urgent needs of the situation, but it was felt that a modification of the University regulations to meet this point is necessary. Provision for students to submit secret war work in a dissertation for a higher degree has been made with apparent success in other universities, notably Oxford. Apart from secrecy precautions, there are difficulties in assessing a student's work if he has been working in a research team or has been engaged on a number of small isolated problems.

The crux of the matter was brought out by one speaker who gave a definition of war research. Scientific work can only be considered as war work when it is *very probable* that it will give results which can be applied to *this* War. Any other form of research is either 'pseudo' war work, or not war work at all. In particular, the urgent need for technical advance in the present critical war situation must be realized. Probably the prime need is for individuals to appreciate their responsibilities to the nation, and themselves actively set about obtaining definite war problems. Difficulties, often considerable, do exist, but they must be expected and overcome. Many university scientific workers need to change their outlook and stop looking for a major research project in short-term pieces of work. Much of the difficulty arises because academic scientific workers are tempted too much to pick and choose their subjects for research. The essential thing now is the usefulness of the research, not its inherent scientific interest. They should be prepared to change over to completely new fields if there is little of direct application in their own, or even to take up work of a more routine nature. A man called up into the Forces has to learn a completely new art, so why not the man of science, who after all is in a sheltered position in the War ?

While the meeting emphasized the need for personal initiative and hard work on the part of the individual man of science, it was clearly in no doubt that the setting up of a national body with executive power to plan scientific work is long overdue. A resolution, which was unanimously carried, gave expression to this opinion by supporting wholeheartedly the demands for a Joint Technical Board or Technical Planning Committee "with executive authority to co-ordinate research, design and development", and pointed out the necessity for such a body having the closest contacts with rank-and-file scientific workers. The maximum effort of Cambridge men of science to help the war effort was promised, and it was urged that, subject to necessary conditions of secrecy, *all* scientific workers engaged on similar problems or employed in the same place shall meet regularly to discuss progress and plan future advance.

COBALT-NICKEL DEPOSITION

AN article in the *Electrical Review* of July 3 by C. C. Downie describes the developments which have taken place in the last three years on research into the deposition of cobalt-nickel alloy. This alloy is at least three times as hard as nickel itself, and is more resistant to corrosion than either cobalt or nickel alone. Moreover, the process is within the bright plating category which obviates the need for subsequent buffing or polishing. The nickel used is electro-refined wire or strip and is even purer than the product obtainable from the carbonyl process. The best metallic cobalt to use is that obtained by special reduction of the oxide, such as by the Kalmus process, which is completely free from carbon and practically all other solid impurities. For all smaller work it suffices to use nickel and cobalt inter-wound in the form of wire or strip, to present a uniform surface closely akin to a solid anode.

Nickel is analysed by the dimethylglyoxime method and cobalt by the nitroso-β-naphthol method. For initial experiments the cathode may be of platinum sheet, so that all features of the deposition at different current densities and concentrations of the two metals can be followed, before commencing operations. The deposits can be made very ductile, so as to bend or twist without any tendency to lift or peel, while what is known as 'double-plate' is rarely encountered.

Earlier work done by Fink and Lah proved the wide range of silver-white deposits which could be obtained from different cobalt-nickel compositions, which in combined chloride-sulphate baths can contain 55–75 per cent of nickel with 45–25 per cent of cobalt. Afterwards, Young and Gould found that the mixed bath can provide almost any desired composition of deposit at a current density of from 10 to 30 amp./sq. ft., with or without agitation. Researches by Brockman and Nowlen showed that the density can be increased to between 32 and 144 amp./sq. ft. with a different type of electrolyte. Advantage has been taken of a similar composition for the dual deposition in a bath consisting (in oz./gal.) of 26·1 nickel sulphate crystals, 4·7 cobalt sulphate crystals, 2 sodium chloride, and 3·25 boric acid, maintained at 20° at a pH value of 5·5–5·8 at a maximum of 30 amp./sq. ft.

This composition gives appreciable control of the two metals, for if the temperature of the bath be increased the proportion of cobalt will be increased with a corresponding diminution of the nickel. Alternatively, by increasing the speed of rotation of the cathode, the nickel proportion can again be decreased. To reduce the cobalt proportion the current density only need be suitably decreased, while by lowering the pH towards acidity the alloy deposited acquires directly an increased nickel content at the expense of the cobalt. The introduction of triethanolamine makes it possible to deposit almost any proportions of cobalt and nickel.

The composition of such alkaline baths (in oz./gal.) is 10·7 nickel sulphate crystals, 4 nickel chloride crystals, 4 anhydrous sodium sulphate, and 16 triethanolamine, together with a second solution composed of 10·7 cobalt sulphate crystals, and 13·5 triethanolamine. In the latter instance the temperature of the bath is maintained at 23° C. and the two solutions are added in measured proportions as required. The corrosion-resisting properties of the combined cobalt-nickel deposit by far exceed those of the constituent metals, while the range of hardness, ductility and toughness is still further increased. The last two mentioned qualities are of special importance in the plating of stereotypes, where brightness is of no great account. The printing surface must withstand wear for lengthy periods without deteriorating, in which respect cobalt-nickel deposit has been of great practical value. The same type of deposit has been applied to the manufacture of rayon and other artificial silks, to surfaces which are exposed to heavy wear in regular textile mills and in modern laundry practice. In various instruments, automatic machines, and the finer parts of acoustic devices, cobalt-nickel deposit is preferred on account of the wide range of physical properties available.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT CHEMIST (MALE OR FEMALE)—The Clerk and Manager, West Midlands Joint Electricity Authority, Phœnix Buildings, Dudley Road, Wolverhampton (endorsed 'Assistant Chemist') (August 14).

LECTURER IN ENGINEERING at the Walker Technical College, Oakengates—The Secretary for Education, Education Office, County Buildings, Shrewsbury (August 15).

GRADUATE LECTURER IN BIOLOGY at the Crumlin Mining and Technical College—The Director of Education, Higher Education Department, County Hall, Newport, Mon. (August 15).

ENGINEER AND SECRETARY TO THE ISLE OF MAN ELECTRICITY BOARD—The Chairman of the Isle of Man Electricity Board, Electric House, Circular Road, Douglas, Isle of Man (endorsed 'Appointment of Engineer and Secretary') (August 17).

GRADUATE LECTURERS IN MECHANICAL AND ELECTRICAL ENGINEERING at the Lincoln Technical College—The Director of Education, City Education Office, 4 Lindum Road, Lincoln (August 17).

ASSISTANT TO THE CHIEF RESEARCH OFFICER OF THE MENTAL DISEASE RESEARCH DEPARTMENT—The Secretary, The University, Birmingham (September 1).

UNIVERSITY CHAIR OF CHEMISTRY, tenable at the Royal Cancer Hospital—The Academic Registrar, University of London, Richmond College, Richmond, Surrey (September 1).

DIETITIAN—The Secretary, University College Hospital, Gower Street, London, W.C.1.

GRADUATE ASSISTANT MASTER TO TEACH CHEMISTRY in the Bury Municipal (Evening) Technical College and **GENERAL SCIENCE SUBJECTS** in the Bury Junior (Day) Technical School—The Director of Education, Education Offices, Bury.

TEACHER IN ENGINEERING—The Principal, County Technical College, Gainsborough, Lincs.

SCIENTIFIC ASSISTANT (WOMAN), WITH KNOWLEDGE OF LANGUAGES AND UNIVERSITY STANDARD QUALIFICATIONS IN PLANT SCIENCE—The Deputy Director, Imperial Forestry Bureau, Oxford.

FORTHCOMING EVENTS

Wednesday, August 12

INSTITUTE OF CHEMISTRY (LONDON AND SOUTH EASTERN COUNTIES SECTION) (at Kodak Hall, Harrow), at 6 p.m.—Dr. J. Grant: "Chemist versus Forger".

Friday, August 14

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Geophysical Discussion on "The Figure of the Earth" (to be opened by Sir Gerald Lenox-Conyngham, F.R.S.).

Sunday, August 16

ASSOCIATION OF SCIENTIFIC WORKERS (at the Institution of Mechanical Engineers, Storey's Gate, Westminster, London, S.W.1), at 3 p.m.—Conference on "The Scientific Film and Scientific Film Societies".

UTILIZATION OF SCIENTIFIC AND TECHNICAL RESOURCES

IN the past few weeks, the movement for making fuller use of the scientific and technical man-power of Great Britain in the war effort has been increasingly to the fore. The question was raised in the House of Lords on July 29 by Lord Strabolgi, who expressed the belief that the work of the scientific men attached to various Ministries is departmentalized; the remedy he suggested is a scientific general staff, with wide powers. The Government reply, by Lord Snell, pointed out the difficulty of arranging for an advisory or executive body which would not be responsible to a Minister, although Ministers are expected to assume full responsibility for decisions taken. He said, however, that the Government is continually considering methods of improving the present organization for utilizing the scientific and technical resources of the country. Since then, Captain L. F. Plugge, secretary of the Parliamentary and Scientific Committee, and nineteen other members of Parliament of all parties, have tabled a motion for discussion in the House of Commons urging "the early establishment of a whole-time Central Scientific and Technical Board to co-ordinate research and development in relation to the war effort and to ensure that the experience, knowledge and creative genius of British technicians and scientists exert a more effective influence over the conduct of a highly mechanized war".

The present position with regard to this thorny subject was outlined in NATURE of July 15, p. 65, following upon a spirited letter in *The Times* from Prof. A. V. Hill. The Government's attitude was defined in more detail in the debate in the House of Commons on July 14, when Mr. Oliver Lyttelton, Minister of Production, made a statement on the work of his department. In reading that statement, it is important to realize that the question at issue is not the merit of the scientific work being done, which is indeed of a high order. The crux of the situation is not the standard of work in the departments, but what is happening strategically in the use of the work of all the departments together. It is the old charge of departmentalism and the need for some properly constituted authority, with technical knowledge, centrally placed, that can insist on getting the information that it wants.

The central issue is simple enough, and it was not confused in the two days' debate. Would a central scientific direction in place of the present scattered and unrelated efforts better enable the country to convert its brain-power into the methods and the physical instruments which, as the product of ideas, win wars ? The general trend of the debate was to give an affirmative answer. At present, scientific and technical control is entirely departmental and not central, and usually at a low level, subordinate to administration. For operations, as Prof. A. V. Hill pointed out, planning has been centralized in the Chiefs of Staff organization; for supply in the Ministry of Production; whereas research, design, development and quantitative planning of the use of technical resources are altogether unrepresented at the highest level.

Prof. Hill's contention that there is no central technical staff or individual to advise the Cabinet or the Chiefs of Staff directly on the scientific and engineering aspects either of operations or production, or to ensure, on their behalf, that design and development are efficient and far-reaching, was not disputed by the Minister of Production. Mr. Lyttelton's attempt to show that such central direction is unnecessary did not find much support, judging from the tone of subsequent speeches during the debate. The evidence of departmental overlapping, of failure to check advance or effort on wrong lines, to correlate results and make them generally available, of lack of stimulus to the right research and of means of bringing the most important issues to the Government, coupled with the conspicuous neglect to implement the recommendations of the Select Committee on National Expenditure which was repeatedly stressed, remain disturbing.

It is not merely that the main questions as to whether our scientific and technical resources are being effectively used as a homogeneous whole, whether the advice of our committees and advisers is taken, and whether they have the authority to get done the things they advise, remained unanswered. The questions raised in earlier debates in February and in March are still awaiting answers. Prof. Hill pointedly commented once more on the research and development side of work in the Admiralty, but there has been no reply to his inquiry on February 24 regarding the scientific panel which had then been sitting for nine months to examine the scientific and technical departments of the Admiralty. Nothing further was said as to the appointment of three of the ablest scientific people in Great Britain to undertake operational research at the Admiralty, and the suggestion of a director of operational research in the combined operational or general staff has been quietly ignored. "If statesmanship and strategy are not properly provided all the time with accurate knowledge of weapons and equipment, their functions, their limitations, their cost in man-power and material for production, and their availability, we are heading straight for destruction. An expert knowledge of modern arms and their interaction with one another in operations against the enemy is an essential part of the directing brain centre in modern, world-wide technical conflict." These words, with which Prof. Hill in his speech on February 24 built up his case for a General Staff with executive functions, including a technical section of young and able officers, proved prophetic in the light of disasters in Libya. That alone sufficiently endorses the plea for providing on the qualitative side some high-level central body to see that the scientific and technical resources of our departments and the country are properly and effectively used, and that all technical activities of the departments are critically examined and their defects rectified.

The uneasiness on this point will persist while there is such studied indifference to the critical examination of many aspects of production which is contained in the fifty or so reports of the Select Committee on National Expenditure. The work of that Committee has been one of the most striking vindications of the Parliamentary system that has come out of the War, and yet, as Mr. A. Edwards pointed out on March 25, scant attention has been given to its reports, either by the House of Commons or by departments. The same point was made repeatedly in the debate on July 15. Sir Herbert Williams reminded the House that the vital importance of close contact at all stages between those engaged in design and those engaged in production was emphasized in the Committee's Second Report presented on April 18, 1940. His emphatic protest against the failure of Governments and Ministers to give effect to recommendations carefully thought out and based on full evidence was strongly supported by Mr. Price as well as by Sir George Schuster, who quoted from the Prime Minister's own Romanes Lecture at Oxford in 1930 on the functions of Parliament in dealing with economic problems: "Economic problems . . . cannot be solved by any expression, however vehement, of the national will, but only by taking the right action. You cannot cure cancer by a majority."

That is equally true of production, and it is no use pressing for a central scientific directing council unless there is in the Government the will, the vision and the determination to compel action on the ascertained facts, no matter what departmental privileges or other vested interests and private considerations must be overruled. A great Minister must to-day be more than the great advocate of which Bagehot writes. We have to secure that everywhere in control of policy and action there are alert and creative minds alive to the inherent possibilities in technical advance and competent not merely to match and counter, but also to surpass the developments and innovations of the enemy. Those are the standards, not social status, by which we must measure the competence, efficiency and dynamic qualities of an individual or a department, and while we may welcome the Minister of Production's assurance that an investigation is being made into scientific organization, and that of the Minister of Supply regarding the equipment for scientific research under the Tank Board, as well as for development and for practical knowledge of all kinds, the latest developments in the organization of the Ministry of Production will by themselves not meet the situation, though they are welcomed and will be followed with a lively interest.

There is no evidence of any desire to insist on the precise form in which the need for central scientific direction should be met. Since the debate an important deputation from the Parliamentary and Scientific Committee has waited on Mr. R. A. Butler, chairman of the Scientific Advisory Committee and president of the Board of Education, and asked the Government to set up a full-time Scientific and Technical Board (NATURE, July 25, p. 116), which would bring together all the essential information that is available, to link up the scientific and technical direction of the departments connected with the War and to influence the War Cabinet and the Chiefs of Staff as necessary.

On a further point also Prof. Hill has clearly won support for his views. He has directed attention to the contrast between our own haphazard system and what is being done in the United States to ensure that the best scientific ability works with the high command. The growing importance of linking our production and resources as closely as possible with those in the United States, the very account of the formation and work of the Combined Production and Resources Board which Mr. Lyttelton gave in his own speech, emphasize the importance of improving organization and relations at this point. But there is no properly organized central agency for bringing together the work of all the missions to the United States. We cannot wisely allow the departments to continue individually to send their missions, not in contact with one another and not co-ordinated with each other's activities. With central technical direction, it would be easy to establish a central information bureau from which scientific and technical liaison could be conducted so as to ensure that departmental missions are at least in touch with one another and that people at the centre know what all of them are doing.

The latest report of the Select Committee on National Expenditure heavily underlines all that has been said in these debates about our lack of full use of scientific knowledge, our tendency to use it as a last resource instead of in the earliest stages, and of the need for what Mr. P. L. Horabin described as a Ministry of Efficiency. If in such matters the Select Committee can advance such a damning indictment of the neglect by the Ministry of Supply of the elementary technique, tools and principles of scientific management few will be so far reassured by the Minister's statements in the debate on production as to cease to press for further co-ordination in matters affecting the use of scientific or technical knowledge.

It is true indeed that we need to become as a nation more achievement-minded, and that the wise use of industrial psychology and effective personnel management in the factory might do much to see better results from the labour force already deployed in the factories. That, however, is only a special aspect of scientific management which industry has long been accustomed to employ, although as the Select Committee observes, only within the last twelve months has there been in the ordnance factories any organized labour management as it is understood in well-run private industry. What is in fact required in the whole field of production, in its qualitative and in its quantitative aspects, is the thorough-going application of exactly those principles of administration which private industry is accustomed to apply unceasingly: far-sighted planning; effective co-ordination and sound organization; effective machinery to ensure that action is taken in accordance with decisions and policy determined; systematic control of efficiency; and the clear delegation of responsibility and the endowment with and use of adequate authority at every point in the chain. Flexibility, decision and purposeful action, co-ordinated and inspired by wise leadership, these are the essentials in war production, and great as have been many of our achievements in the last three years, our effort halts of its maximum until their influence is felt in every phase of our war production and every corner of the national economy.

The attention now rightly being directed to the place of scientific and technical men in the war effort, and the scrutiny of our own organization to that end in the light of American experience, should not lead us to overlook the fact that failure to implement the suggestions or to utilize effectively the knowledge or experience of men of science are only one aspect of a general failing. The memorandum presented to the Minister of Production last March by the Council of the Institution of Production Engineers on "Increasing Production without Increasing Facilities", like the reports of the Select Committee on National Expenditure, testifies to this. Its suggestions for increasing machine activity, regarding the simplification of design, rationalization by standardizing on fewer types or by sub-dividing production between fewer firms, and the introduction of improved manufacturing methods, have for the most part already been advanced by the Select Committee or elsewhere, but it is clear that inadequate use is still being made of the services of the members of the Institution although their availability has long been brought to the notice of the Ministry.

Very clearly, matters cannot and will not be allowed to rest as they are. However capable the president of the Board of Education may be, he ought not to be asked to combine with his departmental duties and responsibilities those which the chairmanship of the Scientific Advisory Committee should involve if that body is to make the maximum contribution towards resolving the present hiatus between expert knowledge and effective action. Whether or not the plan of a joint Technical Board is adopted, it is essential that those responsible for effecting the necessary co-ordination should be freed from other duties and able to devote their full time to the work. The second essential condition is that, individually and collectively, the members of the co-ordinating body should possess the scope and the authority to exercise leadership, and not merely advisory functions. They must be able to compel attention to the scientific and technical issues that come before them, and to override any attempt at departmental delay or frustration.

The establishment of some such small body is the surest way of ensuring that the best use is made of the scientific and technical resources of Great Britain in all branches of the war effort. That establishment, and the steady functioning of such a board when established, will call for unceasing pressure and vigilance from the general body of scientific workers, as well as from that increasing section of the general public which is now becoming aware of the dangerous consequences which have flowed from the Government's failure to deal with departmentalism and to heed the repeated warnings of disinterested and expert opinion of all kinds in matters affecting the efficiency of production and the utilization of expert knowledge.

THE STUDY OF RACE

Race, Reason and Rubbish

By Dr. Gunnar Dahlberg. Translated from the Swedish by Prof. Lancelot Hogben. Pp. 240. (London: George Allen and Unwin, Ltd., 1942.) 8*s.* 6*d.* net.

Race and Racism

By Ruth Benedict. Pp. viii+175. (London: George Routledge and Sons, Ltd., 1942.) 7*s.* 6*d.* net.

NEARLY all proposed solutions of problems of zoological classification have been of provisional value only. Of all such problems, the discrimination of natural subgroups of modern man and the evaluation of their interrelationships must have been the most discussed and the most controversial. The relevant evidence is far more extensive for *Homo sapiens* than for any other species, but no agreement regarding its racial classification has yet been reached. Darwinism altered the course of the study, but it did not provide a solution. More recently, reconsideration has been necessitated by the rapid increase of knowledge regarding heredity.

Prof. Dahlberg's book provides a lucid discussion of those aspects of genetical fact and theory which have a bearing on the racial problem. It is not assumed that the reader has any acquaintance with the subject. The first half of the volume, dealing with the mechanism of individual inheritance in general, is followed by chapters on differences between human populations. Finally, the "rubbish" referred to in the title is discussed: this is the Nazi racial doctrine and its application to Jews in particular.

There is no other account of modern genetics which has the same scope, and it will be welcomed especially by anthropologists. While appreciating that the evidence in question is relevant, they may reflect that it serves rather to emphasize the complexity of their racial problem than to provide a solution of it. In common with many other geneticists who have recently discussed problems of group heredity in man, Prof. Dahlberg considers populations as "isolates", though it is admitted that "species are the smallest groups which have sharp boundaries". In fact, there is no evidence that any subgroup of the existing species of man was detached from all other subgroups at any period. The general rule is that the geographical distributions of anthropological characters show gradations, and they fail to make any abrupt distinctions between populations. The records relating to series of living people and skeletons fail to suggest that any biologically isolated communities have ever existed, and this is the peculiar difficulty of racial classification. In view of a descriptive situation of this kind, the anthropologist may feel disappointed when the geneticist remarks: "Unless a racial group constitutes an isolate, or was formerly one and is now in process of breaking up, it has obviously no special interest for us."

One kind of aid which genetical theory can give to those engaged in dealing with this involved problem is well illustrated by a discussion in "Race, Reason and Rubbish" of the stature of Swedes in modern times. As for several other European populations, the records show that there has been a secular increase in the average measurement since about 1850. This trend has often been attributed to nutritional and other improvements in the standard of living, though there are objections to such an explanation. An alternative one suggested is that the change has been a result of the breaking up of isolates. The tentative argument is:

"Stature depends on a number of genes which reinforce one another. It is reasonable to assume that different genes occur with different frequencies in different isolates. Through the break-up of isolates these genes have been spread out in single dosage. If tallness depends on dominant genes, the break-up of isolates must, therefore, bring about increase of stature." If this view is correct, then stature still fails to satisfy the ideal requirements of a character used for taxonomic purposes.

Scientific workers have been unable to reach agreement in defining the concept of race, or in deriving a particular racial classification. They have no core of established opinion regarding such questions which might have been incorporated in the educational tradition. This failure left the way open to those who supposed that group relationships may be inferred not from biological facts, but from the cultural evidence of early historical records and language distinctions. It was discovered later that the idea of race may be used (or misused) to serve the political purposes of national propaganda.

"Race and Racism" is concerned primarily with this last question. It is divided into two parts. The first gives a popular account of the facts regarding racial differences which are commonly set forth by teachers of anthropology. It deals with such questions as the physical characters used, their genetical interpretation, group differences in mental traits, and the effects of the migrations and minglings of peoples. The treatment of these topics adequately refutes certain misconceptions and falsifications of the evidence, but it leaves the impression that the concept of race is still ill-defined.

The second part of the book deals with "racism", which is said to be "the dogma that one ethnic group is condemned by Nature to congenital inferiority and another group is destined to congenital superiority". This is considered as a communal belief, like a religion, which must be studied historically. Its descent is traced through classical and medieval times to the age of European expansion, and on to the culmination reached in the Third Reich. It is convenient to have a single word to denote the idea of group antagonism, but it may be questioned whether "racism" is the right word. Race did not become a political cypher until it was used in the interests of particular nations during the decades following the Napoleonic wars.

In order to counteract its misuse, Dr. Benedict urges the plea voiced by all detached students who have seriously considered the matter. The need is for widespread teaching of the biological facts of race and their bearing on the origin and development of culture. It is emphasized that such teaching by itself could not be expected to go far towards fostering racial tolerance. To serve that purpose effectively, it should be part of a syllabus concerned with the functioning and ideals of a democratic social order.

Racial dogma had been of political significance in Germany in earlier times, but it was left to the Nazi party to adopt it as the basis of the avowed national policy. The form of the doctrine was specially adapted to excuse persecution of Jews. Beyond that, in fact, no attempt was made to apply the theory: when the henchmen of the Führer were selected, no regard can have been paid to the physical qualities said to indicate pure Nordic descent. But it must have been supposed that the ruse worked sufficiently well, for, otherwise, another would doubtless have been substituted for it. It was possible to exploit the idea of race for propaganda purposes because its scientific investigation had led to no precise and final results. By ruthlessly disregarding all inconvenient facts, it was possible to adapt the doctrine to the changing needs of the political scene. In essence it was anti-scientific and in application entirely unscrupulous. This is a question which might well be considered by those engaged in examining the social and international relations of science.

ACOUSTICAL FACTORS IN PLANNING BUILDINGS

Practical Acoustics and Planning against Noise

By Hope Bagenal. Pp. xi+146. (London : Methuen and Co., Ltd., 1942.) 7*s*. 6*d*. net.

IN buildings of almost every type acoustical problems may arise in one form or another, ranging from the avoidance of noise from neighbours in small houses and flats to the provision of good hearing conditions in concert halls and cathedrals. It cannot be repeated too often that acoustical requirements should be considered from the very beginning of planning, and should be given due weight compared with other factors which affect the general lay-out, form and construction of the building. Mr. Bagenal, writing for students, and also for builders and architects with practical problems before them, expounds this principle very effectively in the book under notice.

The avoidance of noise is often the main acoustical need. In small buildings it may only be the noise of neighbours or of the plumbing, but in larger buildings more sources of noise, such as lifts and air-conditioning plant, may have to be considered. Moreover, different types of building—hotels, offices, hospitals, etc.—present their own special problems. These and other buildings are considered in detail, and the most effective methods of avoiding noise in the initial planning, so as to minimize the need for special sound-insulating constructions, are explained. The methods of providing good sound insulation in partitions, and good insulation against impact noises in floors, are described, and details of practical forms of construction are illustrated.

The last half of the book is devoted to the other major acoustical problem, that of providing good hearing in auditoriums. Here the requirements are adequate loudness, absence of echoes (especially of concentrated echoes arising from focusing of sound by large concave surfaces), and reverberant conditions appropriate to the functions of the particular auditorium. These factors are considered both in general and with special reference to different types of auditorium ranging from the small committee room to the large concert hall.

The author is at his best in dealing with the practical aspects of his subject, and makes effective use of existing buildings in illustrating his points. The short chapter surveying the acoustical defects of modern building types is especially valuable, and could be read with advantage by all members of building committees. Acoustical requirements may conflict with other needs, but they must never be ignored in the hope that everything will turn out satisfactorily in the end. Attempting to design for a multiplicity of functions may lead to failure to provide satisfactorily for any one, and the author wisely advises against such features as suites of committee rooms with folding partitions to permit them to be thrown into one, or a greater and a lesser hall, communicating for large assemblies, but intended also for separate simultaneous use.

The weakest part of the book is that devoted to the theory of building acoustics, and the physicist will find much to criticize here. The 'phon' and the 'decibel' are old stumbling blocks, and Bagenal fails to surmount them successfully. His statement (p. 64) that "where noise measurements of the insulation of a wall or floor are made by comparing energies measured on the source side and then on the receiving side, that is, where they are *differences* between measurements, it is clear that either unit can be used" is quite wrong. At low frequencies the sound reduction in decibels may be very different from the sound reduction in phons ; the former, moreover, is independent of the absolute level of the sound intensity but the latter is not. Similarly (p. 88), the reverberation period of an auditorium is the time taken for sound to decay by 60 db., and is not in general the same as that for a sound of loudness 60 phons to decay to inaudibility. In the table on p. 97 the absorption coefficients of surfaces are specified as being in foot units. The absorption coefficient of a surface is a pure number and thus independent of any units, and the same coefficients are applicable whether areas are measured in square feet or square metres. (The units are rightly stated in dealing with persons, chairs, etc., for the numbers here are the areas of totally absorbing surface which would provide the same absorption.)

These defects are unfortunate in a book intended for students, and the theoretical grounding should be sought elsewhere. Nevertheless, the student, the builder and the architect will all find the book of great assistance, not only in indicating the methods of dealing with specific cases, but also in directing their ideas generally along the lines to be followed in approaching all problems in building acoustics.

N. FLEMING.

AUTOBIOGRAPHY OF AN INDIAN CHIEF

Smoke from their Fires

The Life of a Kwakiutl Chief. By Prof. Clennan S. Ford. (Institute of Human Relations, Yale University.) Pp. xiv+248+4 plates. (New Haven, Conn. : Yale University Press ; London : Oxford University Press, 1941.) 18*s*. 6*d*.

ONE of the interesting features of this book lies in the fact that it covers the period of the first impact of white civilization on the native culture. The story is told by Charley, a Kwakiutl chief, born before there was much change in the native mode of life. Owing, however, to his elder brother's admiration of the white people's civilization, Charley was sent to school where he learnt English, and was thus able to give an account of his own life-history. He must have been a man of exceptional intelligence as well as possessing the good memory which characterizes peoples who have no written language and therefore have to depend upon oral tradition.

Charley's story of his life is no mere catalogue of events, but a full and reasoned account that illustrates, as it goes on, the social and material culture of his tribe, and many of their customs appear under a new light with his explanations of their meaning. This method of presentation is interesting and gives one the feeling almost of personal contact with the tribe, but it has the disadvantages of a good deal of repetition and a sometimes cloying amount of detail. This, however, is probably unavoidable in the circumstances, as over-editing and precise arrangement would destroy its human touch.

Apart from the sequence of nurture from birth to manhood, perhaps the most interesting part of the book is that which deals with the ceremonial life of the Kwakiutl and especially with the holding of the potlach. Charley was a firm believer in these and was at great pains to describe their procedure and significance. Even after they were forbidden by law he continued to hold them, or their equivalents, and thus they are probably the last to be documented by an actual participant. The potlach was no indiscriminate distribution of gifts—usually blankets—but an ordered ceremony in which the rank of each guest was indicated by the number of blankets he received. Each important step in the life of an individual was marked by a potlach, and could scarcely be achieved without it. The more important the status of the donor, the larger the gifts, and thousands of blankets changed hands at a sitting. As a blanket represented wealth and could always be exchanged for other goods, a man's position could be estimated by the number of blankets he owned—or were owing to him, for frequently blankets had to be borrowed, at a high rate of interest, by a man who wished to give a potlach. Moreover, as a man expected, sooner or later, to receive back from each of his guests the same number of blankets that he had given them, a potlach ceremony might be regarded as a kind of investment with the goods still in active circulation instead of being hoarded uselessly. These blankets were originally of native manufacture, of woven cedar bark or of skin; but with the coming of the whites they were soon superseded by the Hudson's Bay Company's trade blankets, which could be obtained readily in exchange for pelts. Potlaches did not always involve the distribution of blankets, for money, canoes or other recognized articles might be used, and at the potlach that took place a few years after a wedding in connexion with the marriage payment by the bride's family, there was always a distribution of household articles—boxes, mats, baskets and such-like.

In spite of his association with white people which was lifelong though intermittent, Charley retained his belief in sorcery, which in his youth was widely practised. The sorcerer, as is usual, had first to obtain some samples of the personal belongings of the individual to be bewitched—such as hair or nail clippings—which were put inside a human corpse, if possible, or if not into the body of some dead animal, which was sealed up and exposed. Whatever happened thereafter to this body would affect the sorcered person, and at its decay the victim would die, unless someone found the corpse and removed the contents. Sorcery was a dangerous trade and liable to punishment by death if discovered, but it was carried on all the same, and Charley gives a good many examples of it throughout his narrative, including his own experiences when a love charm was worked on him by a woman.

Charley must have been one of the last of his tribe to undergo the rigorous initiation ceremonies then practised on boys, including the warrior's dance when twigs were inserted through his flesh and he was lifted by them and was also cut by knives. He said that he felt scarcely any pain at all; indeed the whole boyhood training involved a stoical attitude towards suffering, a trait he seems to have retained throughout his life, as when he was nearly seventy years old he insisted on undergoing two operations to his hand without an anæsthetic.

Perhaps the most important part of the book to students is the author's forty-page introduction, which gives a clear account of the Kwakiutl, their tribal customs and social fabric. Without this, Charley's narrative would lose much of its value, and it provides a concise summary of a North-western culture. As a book of reference, this volume's usefulness is impaired by the lack of an index.

K. Rishbeth.

DERIVATION OF PETROLEUM

Source Beds of Petroleum

By Parker D. Trask and H. Whitman Patnode. Report of Investigation supported jointly by the American Petroleum Institute and the Geological Survey of the United States Department of the Interior, from 1931 to 1941. Pp. xiv+566. (Tulsa, Okla.: American Association of Petroleum Geologists, 1942.) 4.50 dollars.

Although a great deal has been written concerning the probable origin of oil, relatively little has hitherto been published on the nature of the substances from which it is derived. This has been largely due to the scarcity of data relating to the organic constituents of sediments. In 1926 the American Petroleum Institute, recognizing the vital need for such information, instituted a comprehensive study of source beds. Afterwards, in collaboration with the United States Geological Survey, the Institute extended this study of lithified deposits to embrace all aspects of the problem of origin and environment of source beds of petroleum. Results of these investigations are fully reported in this publication and an indication is given of the lines on which further research might profitably be undertaken.

As a basis of correlation approximately 35,000 samples were examined, of which 32,000 were well samples and 3,000 were outcrop samples. Of these 14,000 were from California, 6,000 from the Mid-Continent, 500 from West Texas, 3,500 from East Texas Basin, 2,000 from the Gulf Coast and 3,000 from the Appalachian area.

The method of examination was to compare the properties of the sediments within 200 feet of the oil zones with those more than 500 feet away to ascertain if consistent differences existed. Because of the large number of samples, attention was focused on properties of sediments which could be determined rapidly and with reasonable accuracy. Eight properties studied were: organic carbon content, nitrogen content, reduction number, assay number, texture, content of bituminous substances, colour and calcium carbonate content.

It was found that the nitrogen-reduction ratio, which is the ratio of the assay number to the reduction number and is a rough measure of the degree of volatility of the organic constituents, had a fairly definite relationship to the occurrence of oil, this ratio being generally low in sediments closely associated with known oil zones and generally high in barren beds or in sediments remote from known oil zones. The ratio ranged mainly between 3·0 and 10·0, and it was concluded that formations in which the average ratio is less than 5·0 could be considered definitely favourable for the finding of petroleum; those in which it is 6·0 were regarded as encouraging; those in which it is 7·0 not particularly encouraging; and those in which it is more than 8·0 definitely unfavourable.

The investigation is not claimed to have solved the problem of source beds, though considerable progress has been made. It is suggested that future research should be more detailed and that special attention should be given to sediments which, because of their stratigraphical relations to known oil zones, are almost certainly source beds. Investigations of this character would involve special chemical and physical methods such as X-ray and ultra-violet ray studies, chemical analyses of organic constituents and determinations of the state of reduction by more refined methods than have hitherto been employed.

PSYCHOLOGICAL STUDY OF TWINS

Twins and Super-Twins

A Study of Twins, Triplets, Quadruplets and Quintuplets. By Prof. Horatio Hackett Newman. (Advancement of Science Series, No. 1.) Pp. 164+15 plates. (London, New York and Melbourne: Hutchinson's Scientific and Technical Publications, 1942.) 10*s.* 6*d.* net.

ALTHOUGH, as the Registrar-General's recent report on fertility shows, one out of every forty-four persons born alive in England and Wales is a twin or super-twin—to use Prof. Newman's convenient term for individuals born more than two at a time—plural births usually occasion surprise and sometimes consternation. It was natural that the first quintuplets known to have been reared should attract popular interest; but it was not anticipated that the Dionne children would rival Niagara Falls as an attraction for foreign visitors to Canada. In writing a book designed to sift fancy from fact and to give a popular account of scientific knowledge about twins and super-twins, the author is sure of a wide circle of readers. It is only possible here to touch upon a few aspects of such a work.

Of the twins born in the United States during 1890–1900, 26 per cent are estimated to have been monozygotic, and the author states that 3–4 times as many dizygotic twins and 6–7 times as many monozygotic twins are born dead as is the case for singly-born children. The 1938 fertility statistics of England and Wales have shown that probably 25·4 per cent of twins born were dizygotic, and that the proportion of still-born was 83 per 1,000 for twins of like sex, 63 for twins of unlike sex and 37 for singly-born children, a very different ratio which does not, however, comprise abortions. The twin frequencies in different countries, set out in Table I, leave the reader in doubt as to the period covered, and nothing is said as to the probable effect of differing maternal age distributions, which have changed rapidly in some countries. This table and the conclusions drawn from it may be misleading, for while Norway is given a frequency of 1·45 twin maternities in each 100, and Italy 1·16, the percentage frequency of multiple maternities in 1934–36 was 1·35 in each of these countries, as a table in the Registrar-General's report indicates. A higher frequency in Scandinavia than in the British Empire (United Kingdom 1·21, Canada 1·18, New Zealand 1·17, South Africa 1·10) or in the United States (1·17) seems to be established by recent figures, but otherwise no firm conclusion can be drawn.

The summary of recent facts about monozygotic twins reared apart and about the Dionne quintuplets is, perhaps, the best part of the book. After ten years of patient search twenty pairs of monozygotic twins who had been separated in infancy and brought up in different circumstances have been found, and studied. Of these, four pairs had experienced wide differences in education, and their discrepancies in intelligence quotient (Stanford-Binet) amounted to 24, 19, 17 and 12 points, whereas in the remaining sixteen pairs whose education had differed only slightly the average discrepancy was no more than that for monozygotic twins reared together. The author's conclusion that the intelligence quotient is not fixed by heredity alone but can be changed considerably by education is a useful corrective to the widely held belief that intelligence quotients are measures of innate ability which are scarcely affected by education or environment. Furthermore, it shows that some conclusions which have been drawn from comparisons between the average intelligence quotient of groups of people educated under widely different circumstances of time and place, as for example parents and their children, are invalid. Innate ability cannot respond fully to most intelligence tests unless there has been an adequate educational background. On the other hand, the maximum response to such tests obtainable by dint of education is definitely limited by capacity of genetic origin, and it is not surprising that, despite the well-nigh perfect conditions of upbringing of the monozygotic Dionne quintuplets, identical hereditary factors seem to be imposing very similar limitations of mental development upon them all.

ENGINEERING MATERIALS

Materials Handbook

An Encyclopedia for Purchasing Agents, Engineers, Executives and Foremen. By George S. Brady. Fourth edition. Pp. vii+591. (New York and London: McGraw-Hill Book Co., Inc., 1940.) 35*s.*

THE sub-title of this handbook gives the clue to the mode of treatment of the subject matter, and so inactivates the critical faculty of anyone who would judge it as a strictly scientific work; but it may at once be said that the information provided, being accurate and clearly presented, will be most useful to the readers for whom it is intended. The author wisely keeps to facts and ignores opinions, and his assiduity in collecting and fashioning the information over a period of twenty years deserves high commendation.

Although errors and omissions are remarkably few, considering the magnitude of the work, attention may usefully be directed to some of them. It will be news to the modern educated engineer to learn that oxalic acid is made by the action of nitric acid on strong alkalis (p. 349), and even a fourth-form schoolboy will smile at the statement that the specific gravity of degras (unpurified wool fat) is about 92 (p. 162). No doubt the latter is an uncorrected printer's error, as also is the formula $NaSO_4$ for saltcake (p. 472), and the statement that benzyl bromide is made by mixing bromide and toluene (p. 63). Trade buyers, executives and foremen, in particular, are unlikely to be edified by the assertion that dextrine is "a starch with a smaller value of x in the molecule"; and though, as the author states, it was clearly impracticable to give references or quote authorities, one would like to have corroboration of the statement that acetic acid occurs in citrus fruits and vegetables (p. 5).

Among the few omissions noted is the absence of any reference to synthetic acetic acid and the manufacture of nitric acid by oxidation of ammonia. There is a great wealth of data concerning metals and alloys, but chemical materials are treated somewhat cavalierly; for example, only eight lines are given to methyl alcohol, fifteen to benzene and seventeen to 'alkalis'; in fact, a better title for the book would be "Handbook of Engineering Materials". British trade names are conspicuously few, but no doubt a limit had to be set to the size of the volume; as it is, no fewer than about 4,500 substances are dealt with, and this fact alone should ensure a wide and successful appeal among those who desire a reliable and reasonably up-to-date compendium of the marketable commodities used in engineering and allied industries.

MODERN STATISTICAL METHODS

The Fundamental Principles of Mathematical Statistics

With Special Reference to the Requirements of Actuaries and Vital Statisticians; and an Outline of a Course in Graduation. By Hugh H. Wolfenden. (Published for the Actuarial Society of America, New York.) Pp. xvi+379. (Toronto: The Macmillan Company of Canada, Ltd., 1942.) 5 dollars.

Sampling Methods in Forestry and Range Management

By F. X. Schumacher and R. A. Chapman. (Duke University School of Forestry, Bulletin 7.) (Durham, N.C.: Duke University Press, 1942.) 2 dollars.

THE contemporary population of the United States seems to have not only a taste but also a distinct genius for statistical research. It does not follow, however, that American mathematicians have at all uniformly shown a talent for expounding mathematical statistics. The contrast is one of the most interesting in contemporary science. Obviously it springs largely from the detachment and isolation of many mathematical departments from the fields of application; so far that expositors do not appreciate, or indeed even know of, the mathematical advances used in practice. This paradoxical situation has, of course, its lessons for other countries and for other disciplines.

Mr. Wolfenden has written an original book. It is scarcely what its title (on the cover) claims, a presentation of "The Fundamental Principles of Mathematical Statistics", but rather an introductory course of reading for actuarial students, and "an Outline of a Course in Graduation". This course, which occupies two thirds of the book, is divided into three sections: (*a*) history; (*b*) mathematics and interpretation; and (*c*) applications.

The stress laid by the author on the importance of history is most refreshing:

"I therefore believe it essential to the proper understanding of any subject to absorb the history of the mental processes which have guided its development. This study, accordingly, is framed on that conviction. It is hoped, however, that the arrangement used will enable the reader to acquire the background easily, and in a manner less destructive of imaginative interest than is so often inseparable from the teaching of history *per se*."

A text-book is often thought to be a suitable sarcophagus in which to lay undisturbed the embalmed remains of obsolete methods. One valuable use of a historical as contrasted with a mathematical section might be to separate the living from the dead. The contributions of the twentieth century have, however, suffered in Mr. Wolfenden's hands. "Student's" method is much ill treated, and I read with pain of the analysis of variance "arising from Lexis's theory, based in fact upon the 'correlation ratio' ". Such comments are not historical. I venture to suggest that the first two hundred papers, at least, employing the analysis of variance do not make any use of Lexis's theory, or of the correlation ratio; and, for such part as I had in developing the method, I was at that time strongly conscious of the failure of the methods developed by Lexis and Pearson to solve even the simpler problems of this type which they discussed.

Whereas Mr. Wolfenden's title seems to invite too wide a class of readers, Schumacher and Chapman's paper-covered bulletin from the School of Forestry at Duke University, entitled "Sampling Methods in Forestry and Range Management", might properly have been addressed to a much wider audience. It constitutes an altogether excellent introduction to modern statistical methods, and its success in this respect seems to flow directly from the fact that the authors' aims are not academic, but are concerned only with a competent planning and handling of this aspect of practical forestry.

The utmost care is taken to give the reader a clear grasp of the elementary concepts which all statistical work involves; but this does not mean that only unimportant ground is covered. Degrees of freedom are introduced in the first chapter; "Student's" method and inferences of fiducial probability appear in the second. Part 2 is concerned with direct estimates by sampling, introducing the effects of the finiteness of the population sampled; stratified random sampling; the simultaneous use of several variates; sub-sampling and representative sampling. Part 3, on indirect estimates, gives a thorough account of the uses of regression, not neglecting the use of weights.

An appendix includes technical notes on mathematical points requiring further discussion than that given in the text. In respect of the factor $\left(1 - \frac{n}{N}\right)$ used in the variance of samples from finite populations, I would suggest that the student can gain a clear idea of its origin from the circumstance that sampling errors only affect his estimate of that fraction of the whole which is not included in the sample. The technical note on this point thus seems unduly heavy.

R. A. Fisher.

MECHANISM OF METALLIC FRICTION*

By DR. F. P. BOWDEN and D. TABOR

Council for Scientific and Industrial Research, Melbourne

AN experimental investigation of the kinetic friction of non-lubricated metals has shown that, in general, friction cannot be regarded as a surface effect. Penetration and distortion occur to some depth beneath the surface, and the frictional force and the nature of sliding are both influenced by the bulk properties of the metals. The physical properties of the metals, such as their relative hardness and melting point, play an important part. In fact, it has been shown that the nature of the sliding and the value of the friction are largely determined by these factors, and it has been suggested[1,2,3,4] that the frictional resistance between unlubricated metals is due primarily to the shearing of the metallic junctions formed by adhesion and welding at the points of contact, and to the work of dragging or ploughing the surface irregularities of the harder metal through the softer one. Even if the metals are carefully polished and are made as flat as possible, hills and valleys which are large compared with the dimensions of a molecule will still be present on the surface, and contact will occur only locally at the summits of these surface irregularities. The formation of metallic junctions between the surfaces will, of course, take place with cold metals. It has been shown that when the speed is slow or when the surfaces are stationary, so that there is no question of temperature rise, the high pressures at the points of contact will readily cause local adhesion and welding.

If the load and speed are sufficiently great, the frictional heat may raise the local surface temperature to a high value, so that a softening or even melting may occur at the points of contact. The occurrence of these high temperatures may be demonstrated by measurements of thermal electromotive force[5] and by polishing experiments[6]. If the loads are relatively light or the sliding speeds are slow, the temperature is, of course, too small to affect sensibly the mechanical properties of the metals. This is made clear in the original papers, where the actual conditions necessary for high temperature have been determined; but it is emphasized here, since there seems to have been some misunderstanding on this point. Other workers[7,8] have reported that when the average sliding speed of the surfaces is slow, the momentary temperature rise is of the order of 30–50° C. These measurements are in sensible agreement with ours. There seems little doubt, however, that under many of the conditions of load and speed used in practice, the local temperatures reach a high value. Independent evidence for the occurrence of these high temperatures has recently been obtained by other observers [9,10,11]. These observations are of importance, since it means that, under these conditions, the frictional behaviour of the metals and of lubricant films on them will be determined not by their properties at room temperature but by their properties at the actual temperature of sliding.

The physical processes that occur during sliding are obviously very complex, but an attempt has been made to put this theory on a more quantitative basis and to make an approximate calculation of the friction in terms of the known physical properties of the metals. It is suggested [12] that we may, in general, write the frictional force F as $F = S + P$, where S is the force required to shear the metallic junctions and P the force required to displace the softer metal from the path of the slider. A simple theoretical treatment enables us to calculate, for sliders of different shapes and sizes, the values of F, S and P in terms of the shear strength s and the 'flow pressure' p of the softer metal. In general, it follows that $S = As$, where A is the real area of contact of the metals, and $P = A'p$, where A' is the cross-sectional area of the torn track. From this, $F = As + A'p$.

If the ploughing term P is negligible, we have $F = As$. When the load is applied to the surface, plastic flow of the softer metal occurs at the regions of contact until the area of contact is sufficiently great to support the load. With any particular metal, therefore, the real area of contact A is determined primarily by the load W, and $W = pA$.

Hence $F = W\frac{s}{p}$, and the coefficient of friction

$$\mu = \frac{F}{W} = \frac{s}{p} = \frac{\text{shear strength}}{\text{flow pressure}}.$$

A somewhat similar expression applied to the cutting of metals has recently been derived by Ernst and Merchant[13].

Friction of a Hard Metal on a Soft One

An experimental investigation was made of these relations for steel sliding on indium, which is a very soft metal. The experiments were made with cylindrical, hemispherical, and plane sliders, and S and P were evaluated separately. The sliding speeds were low, so that the metals were at room temperature. It was found that the experimental results were in reasonable agreement with the general theory. The relative magnitude of the two terms S and P naturally depends upon the shape of the slider and upon other factors, but it is clear, both from theory and experiment, that under many experimental conditions the ploughing term P is an appreciable fraction of the total frictional force.

Another problem that is of general interest is the relation between the frictional force, the area of contact, and the load. The early work of Coulomb and of Amontons led to the formulation of two 'laws': (i) that the frictional force is independent of the area of the sliding bodies; and (ii) that the frictional force is proportional to the applied load[14]. There has been some difficulty in explaining these laws, but experiments on the real area of contact between stationary and between moving surfaces offer a theoretical explanation of them[2]. In these experiments the area of contact between the metals was determined by measuring the electrical conductance between them, and the results showed that, in general, contact occurred only locally at the summit of the surface irregularities, so that the real area of contact was very small and was almost independent of the apparent area of contact. We should therefore expect that the frictional force would also be independent of the apparent area of contact.

The second law, which is often referred to as Amontons' Law, also presented difficulties, since it was usually assumed that when the load was applied the surfaces were deformed elastically. In this case, the area of contact and hence the frictional force would be expected to vary as the two-thirds power of the load and not as the first power[2,15]. The conductivity measurements, however, showed that the deformation of the surfaces is mainly *plastic*[2]. The metals flowed under the applied load until the area of contact was sufficient to support it. In the case of plastic flow, the area of contact is directly proportional to the applied load, so that the difficulty disappears and we should expect the second law (Amontons' Law) to hold.

---

* Lecture given to the Royal Society of Victoria in March 1942.

With any particular junction or point of contact between the metals, one of two conditions may obtain:

(1) The strength of adhesion between the soft metal and the hard may be greater than the shear strength of the soft metal. In this case, the break will occur within the soft metal, and fragments will be left adhering to the surface of the hard one. If the fraction of the total area of contact over which this occurs be α, the frictional resistance due to these junctions will then be $s_1 \alpha A$, where s_1 is the shear strength of the softer metal and A is the real area of contact.

(2) The strength of adhesion at the junction is less than the shear strength of the softer metal. In this case, the break will occur between the metals, and the soft metal will not be wiped on to the harder one. The value for the shear strength of these weaker junctions will not necessarily be constant. It may vary from a value that approaches s_1 down to very small values. Let s_2 be the average value. Over the whole area of contact there will, in general, be junctions of both types, and the total shearing force S will be:

$$S = A\,(s_1 + (1 - \alpha)\,s_2).$$

This treatment has been applied to metals which differ in hardness. The same general considerations apply if the surfaces both consist of the same metal. This case is, however, more difficult experimentally, since it is not easy to evaluate separately the S and P terms. We may expect somewhat similar general conclusions to hold for non-metallic solids.

Effect of Contaminating Films

Under most experimental conditions, metal surfaces are covered with a thin oxide layer and other contaminating films. During sliding, these films are torn, many of the surface irregularities penetrate through them, and some metallic contact does occur. Nevertheless, we should expect that the adhesion and shear strength of the junctions would be less than that of the pure metal. Earlier experiments have shown that this is indeed so[16]. If the surface films are removed by outgassing in a high vacuum, the friction is increased to a high value (for example, for outgassed nickel or tungsten μ is increased from about 0·3 to 6). In the same way, we should expect that the deliberate addition of suitable lubricant films to the metals would again diminish the intimacy of contact and the strength of adhesion at the junction.

Although experiments show this, they also show that lubricant films are rarely able to prevent some metallic adhesion from taking place. The surface irregularities penetrate and tear through the surface film, and metallic seizure and damage occur. The total area over which this metallic seizure takes place is, of course, very much smaller in the presence of lubricants than in their absence. It is probable that the main effect of adding a lubricant is to decrease both α and s_2. The experiments suggest that with clean steel sliding on indium, α is very nearly equal to unity and s_1 to the shear strength of pure indium.

Intermittent Motion

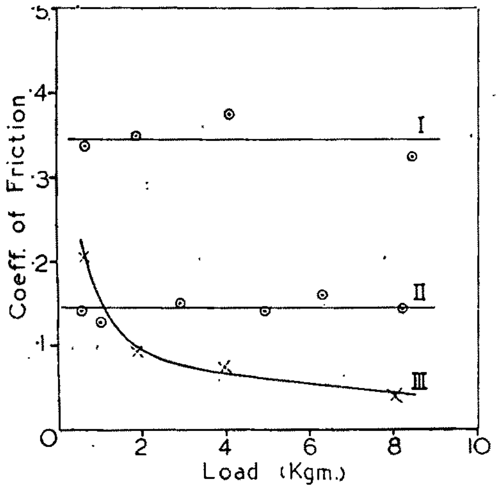
It has been shown that if one part of the moving system possesses an appreciable degree of elastic freedom, the motion may not be continuous but may be intermittent and proceed by a process of 'stick-slip'. This necessarily means that the kinetic friction during the slip is less than the static friction during the stick. It was found that with any particular mechanical system the type of sliding is profoundly influenced by the nature of the metals and of the lubricant films on the surface. The nature of the motion is also, of course, controlled by the mechanical properties of the moving system. Other workers[7,8] have recently repeated some of these experiments, using similar apparatus. They find results which are similar, but they lay particular stress on the fact that the motion is determined by the elastic properties of the system. This has, however, already been emphasized by us (compare ref. 3), where it is stated that the motion "will be influenced by the mechanical properties of the system such as the natural frequency, the moment of inertia, and the damping of the moving parts. Finally, it will be influenced by the velocity of the main forward motion." Since many moving systems possess an appreciable degree of elastic freedom, and since, in the limit, the surface irregularities themselves may be capable of a small elastic deformation, this stick-slip motion is of frequent occurrence provided the surface and other conditions are suitable.

It is not suggested that the occurrence of stick-slip is in itself proof that a lubricant is a poor one, although most poor lubricants give a motion of this type if the mechanical system will permit it. The nature of the sliding, the value of the friction, the damage to the surface and other factors must all be taken into account.

Friction of Metallic Films

In the earlier experiments, Amontons' Law held true, because a variation in the load automatically produced a corresponding change in the area of contact. It was not possible to vary them independently. This may be achieved artificially by using as the lower surface a hard steel substrate on to which a thin layer of a soft metal such as indium is deposited. A hemispherical slider is placed on top of this, different loads are applied, and the friction measured[12]. When the load is applied, the spherical surface will sink through the indium layer until the weight is supported by the underlying steel surface. Since the underlying steel surfaces are deformed comparatively little by the load, further increases in load will have relatively little influence on the area of contact between the slider and the indium. Provided a very thin layer of indium still adheres to the bottom surface so that little or no steel contact occurs, we should expect the frictional force to be almost independent of the applied load. This means that the coefficient of friction as usually defined by $\mu = \frac{F}{W}$ should decrease as the load increases.

Curve I shows the results obtained with unlubricated steel, Curve II with steel lubricated with a mineral oil and Curve III with steel on the surface of which an indium film 4×10^{-4} cm. thick has been deposited. In the first two cases, Amontons' Law is obeyed and μ is constant. With the indium film Amontons' Law breaks down; μ decreases as the load increases and reaches a value so low as $\mu = 0{\cdot}04$. This very low value of the friction is considerably less than that frequently observed with the best boundary lubricants and is similar to that obtained on ice[17].



Friction of curved slider on flat surface. Steel on steel (I) unlubricated, (II) lubricated with mineral oil, (III) with indium film 4×10^{-4} cm. thick.

The frictional force was determined by the real area of contact A between the steel and the indium. The load was important mainly in so far as it affected this area. In fact, for any given track-width the friction was the same on bulk indium as it was on indium films. If, however, very heavy loads were used, the films broke down: contact occurred between the slider and the underlying metal and the friction rose. Similar results were obtained with films of lead and copper deposited on the surface of other metals. It is interesting to note that Attlee, Wilson and Filmer[18] found that the steel ball bearings in a vacuum tube could be lubricated by thin metallic films of softer metals.

Effect of Temperature

With metallic films, the friction decreases steadily as the temperature is raised and reaches a minimum when incipient melting begins. This should be contrasted with the effect of temperature on the friction of pure metals[16], where the change in friction is very much less marked. This is to be expected, since with pure metals the shear strength decreases with temperature; but this is accompanied by a corresponding increase in the area of contact. With metallic films, however, the area of contact remains essentially constant since the load is taken primarily by the hard underlying metal. The decrease in shear strength of the film, therefore, leads to a decrease in friction. Once melting is complete, there is a rise in the friction, the magnitude of which depends upon the extent to which the molten metal wets the underlying surface.

In some ways, the behaviour of thin metallic films closely resembles that of lubricant films. They produce a substantial reduction in the friction, they can cause smooth sliding, and they protect the underlying metal surfaces. In addition, metallic films are worn off the surfaces by successive sliding over the same track in a manner similar to that of a lubricant film, except that the metallic films are worn away at a greater rate than the hydrocarbon films. A further point of similarity is the effect of melting. The transition from smooth sliding to stick-slips when the metallic films are melted is closely analogous to the change observed when solid hydrocarbon films are heated through their melting point[4].

There are, however, several marked differences between metallic films and lubricant films. The earlier experiments[4] showed that even on rough surfaces a lubricant film need only be one molecule thick to be effective as a boundary lubricant (see also Langmuir[19]). A metallic film must be appreciably thicker (*ca.* 10^{-6} cm.) if it is to be effective. A further striking difference is that lubricant films obey Amontons' Law whereas metallic films of this thickness do not. It is possible that with very smooth surfaces considerably thinner metallic films would be effective, and in this case Amontons' Law would be more nearly applicable.

The fact that under suitable conditions metallic films may act as effective lubricants is of some practical interest. It is suggested that the smearing of a thin film over the surface of a hard one plays an essential part in reducing the friction of many bearing alloys. Experiments which have been carried out on some of the copper lead alloys and on silver lead indium alloys lend support to this suggestion.

TEA LEAVES AS A MAINTENANCE FOOD FOR ANIMALS

By W. KING WILSON
Harper Adams Agricultural College

IN these days, when the conservation and utilization of vegetable waste of all kinds is so urgently necessary, it is desirable that the possibilities of feeding spent tea leaves, which are produced in such large quantities, should not be overlooked.

Tea drinking has greatly increased in the United Kingdom in the past century; consumption rose from 1·4 lb. per head a century ago to 9·2 lb. before the War. The next highest rate of consumption per head of population was in the British Commonwealth, namely, Eire 8·2, Australia 7·0, New Zealand 6·7, Canada 3·6. Although total consumption in the United States was high, the rate was only 0·7, in the Soviet Union 0·2 and in Germany 0·2 per person.

It is obvious that in Great Britain the spent tea leaves provide a considerable bulk (roughly 200,000 tons before the War) of waste material which is available in most households and might be utilized, with other waste foodstuffs, for domestic animals.

An idea of the chemical composition of spent tea leaves is given by the following results of analysis of a sample taken from the urn and pots in the kitchen of Harper Adams College. The sample was found to contain 84·2 per cent of water and 15·8 per cent of dry substance, so that a pound of these wet leaves was equivalent to nearly 3 oz. of air-dry meal. The dry matter was found to contain 26·1 per cent crude protein, 14·2 per cent fibre, 1·2 per cent oil, and 4·6 per cent mineral matter. The high percentage of crude protein is probably deceptive since much of it is almost certainly in an indigestible form owing to the rather high tannin content of the leaves. In a test by the method of artificial digestion the dry substance was found to yield only 3·7 per cent of digestible protein. It is probable also that the tannin will tend to reduce the digestibility of the protein in other foods with which tea leaves may be mixed, and this point must be kept in mind in making up rations containing tea leaves. Broadly speaking, from the point of view of composition tea leaves may be regarded as a rough substitute for bran, though rather higher in fibre and lower in digestible protein.

There is a conspicuous absence of data on the use of waste tea leaves in animal rations, although it was indicated that they could be utilized as a result of feeding two small rabbits for very short periods (for five and ten days respectively) with 50 and 33 per cent of meal and bran replaced by an equal weight (30 and 25 gm.) of dried tea leaves. Another one was fed for two periods of ten days each with 33 and 50 per cent (20 and 30 gm.) of the meal and bran replaced by tea leaves. The same rabbit was fed for three days on powdered tea leaves without diminution of weight[1].

The use of spent tea leaves is no novelty to small-scale rabbit-keepers, but definite evidence as to their worth seems, however, to be very scanty, and therefore in view of the present emergency it was thought worth while to make some controlled tests in the Rabbit Section of the National Institute of Poultry Husbandry. The tea leaves were taken daily straight from the drainer and fed as soon as possible since they quickly go mouldy, especially in hot weather. They were readily taken by the rabbits, and their consumption reduced the intake of drinking water and stimulated the consumption of hay.

Tea Leaves in Growers' Rations

The first trial, of which a preliminary report has been given in the technical press, was carried out with thirty young rabbits, divided into three groups of similar weight (average 3 lb.). The control group were fed on green food, dry meals and rough hay. The other two groups were fed high proportions of tea leaves, 25 and 50 per cent of the concentrates being replaced on the basis of 4 oz. of tea leaves replacing 1 oz. of meal. It was found necessary to reduce the quantity of green food owing to undue laxativeness when used with high proportions of tea leaves. After one week on these diets the average weight gains per head were 4·5, 2·8 and 0·2 oz., but as the 50 per cent group had also dropped badly in condition the proportion of tea leaves for this group was reduced to a 12½ per cent replacement level, after which they soon recovered and then made satisfactory progress. By the end of the fourth week it was clear that even 25 per cent substitution was excessive, whereas those on 12·5 per cent replacement were doing well, with glossy fur and good bodily condition, and by the end of six weeks their average live weight had practically caught up with those of the controls, namely, 12·2 and 12·6 oz. respectively.

Briefly summarized, therefore, the first experiment with growers indicated that 12·5 per cent of the concentrates could be replaced by fresh spent tea leaves, but a 25 per cent level proved unsuitable between two and four weeks, and at 50 per cent it proved unsatisfactory within one week.

A second experiment was made with thirty more young rabbits, divided again into three groups of similar live weight and fed thus: group (4) on the control diet, (5) with 12·5 per cent of the concentrates replaced by fresh spent tea leaves, and (6) also with 12·5 per cent concentrates replaced by tea leaves but supplemented with fish meal in the ratio of 16 to 1 by weight to raise the protein level to that of the controls. The latter produced softer fæces than groups (4) and (5). Body condition and fur growth appeared to be similar 4–6 weeks later but, when handled, group (5) was not so good as the control or the supplemented tea leaves group; the latter were in good, firm condition. At the end of the sixth week of the experiment the average weight increments per head for the three groups were 12·3, 11·8 and 12·6 oz. respectively.

These results thus confirm the conclusion from the first experiment carried out that for growers, up to 12·5 per cent of the concentrates could be replaced by tea leaves.

Tea Leaves in Maintenance Rations

In a third experiment the object aimed at was to ascertain the extent to which this substitute foodstuff could be utilized in winter maintenance rations when other feeding-stuffs were in short supply. After a preliminary feeding period of two lunar months thirty adults, of average weight 7 lb. 7·6 oz., were divided into three comparable groups. Lot (7), the control group, was given a daily allowance per head of green food 7–11 oz., coarse hay 1·7 oz. and concentrates 3·6–2 oz., varied according to their condition and appetites ; lots (8) and (9) were similarly fed except that 10 and 20 per cent, respectively, of the concentrates were replaced by tea leaves (on the 4 : 1 basis) supplemented by 6 per cent of fish meal. The concentrates were fed generously in the early periods, when practically all stock was heavy in the moult, and were later reduced, more greenstuff or roots then being fed. The average daily food consumption in each lunar month is shown in Table 1. Owing to shortage in the supply of tea leaves during the College vacation, there was a break of three weeks in the feeding between the second and third months.

3rd month ..	8	6·50	7	13·50	7	10·90
4th ,, ..	8	2·90	7	10·50	7	8·80
5th ,, ..	8	1·20	7	12·00	7	8·10
6th ,, ..	8	8·70	8	0·00	7	10·10
7th ,, ..	8	11·20	8	2·40	7	14·50
Actual aver. gain	1	1·90		9·60		6·70

From the live weight data summarized in Table 2 it will be seen that during the first two months the average gains in live weight per head in the three groups were 8·9, 1·5 and 1·7 oz. respectively, which suggests that the control ration was more than adequate for maintenance and produced a certain amount of fattening, while the two tea-leaves groups seemed little more than bare maintenance. After the experimental feeding was resumed at the beginning of the third month the differences over the remaining five months were much less (9·0, 8·1, 5·0 oz.), there being in fact little difference between the control group and the 10 per cent tea-leaves group, although the 20 per cent group was still substantially behind the others. Over the whole experiment the average weight gains of the groups with concentrates replaced by tea leaves were 53–63 and 37–43 per cent respectively of that of the control group.

The condition of the groups was mainly good to very good. The fur underwent great change, from heavy moult in all groups at the start, to a good, even, glossy fur in each group by 3–4 months later without any noticeable difference between different rations. The full winter bloom later faded as the breeding season came round. In the last month the does were mated and the feeding of tea leaves ended before the birth of the young. The numbers of fertile does in each group in this round of matings were eight, seven and nine respectively, so that the tea-leaves would not seem to have exercised any specific effect, either good or bad, on fertility. There were strong indications that the infertile does in all groups were associated more with strain than feeding.

As was to be expected, a much higher proportion of water was drunk by the control animals, with their somewhat larger quantity of dry food, than by those eating fresh moist tea leaves. The average daily amounts of water taken were 5·19, 3·26 and 3·26 oz. respectively. The water intake was also influenced by the quantity of roots and greenstuff which was fed. The animals on the tea leaves had damper floors, especially on the 20 per cent replacement, and required more hutch cleaning and caused some coat stain on the lower part of the body fur.

Briefly summarized, this experiment indicated that adult rabbits could be maintained in body condition on a ration in which 10–20 per cent of the concentrates were replaced by spent tea leaves (on the 4 : 1 basis). There was an increase of live weight in all groups, being greatest on the control diet, and lowest on 20 per cent replacement of concentrates by the tea leaves mixture. In neither case was there any adverse effect on subsequent fertility.

Acknowledgment is made of the helpful advice received from Dr. Charles Crowther in connexion with these experiments.

BRITISH ASSOCIATION CONFERENCE ON MINERAL RESOURCES*

THE second day of the Conference convened by the British Association Division for the Social and Industrial Relations of Science on July 24–25 was marked by the presence of Sir Stafford Cripps as chairman of the afternoon session. In his opening remarks Sir Stafford alluded to his own experience of chemical research under Sir William Ramsay and to his contacts with scientific problems in the course of legal practice. It had been said that technical invention had outstripped social and political invention and means had still to be found by which the knowledge of the technical experts could be fully utilized in a democratic organization. It was not desirable that Parliament should be composed of specialists, the 'common jury' mind, capable of forming a general judgment on wide problems, being of great value, but that judgment had often to be formed on a basis of scientific evidence or technical knowledge. The Atlantic Charter was an attempt to express in easily understood terms the direction in which the political leaders of the democracies were looking for progress after the War had been won. It was clear that in its application a multitude of questions would be raised, requiring the best brains for their solution.

However perfect the planning of the future by experts might be, it would be of no avail without the determination of the peoples of all nations that it should succeed. It could be destroyed by a return to the old competitive struggle between nations or corporations in an attempt to win monopolies, and it would be necessary for the United Nations to undertake international regulation of the production and distribution of raw materials, in the interest of the devastated countries as well as with the object of attaining a rising standard of living throughout the world. The proposed international organization for the mobilization of all available knowledge of natural resources would be a valuable factor. The pooling of knowledge, already long customary in the field of research, must now be translated into co-operative action. The co-ordinated and planned action which had been essential during the War would be no less so after it, and the step from economic warfare to economic welfare would have to be taken. Science had shown the way to an economy of plenty, and its possibility had been made clearer by the events of the War.

---

* Continued from p. 173.

At the morning session the chairman Dr. C. H. Desch, spoke of new metals and new methods. The importance of the influence of small additions of special elements to metals on their properties was illustrated, not only by the example of the alloy steels but also by such applications as the hardening of copper by beryllium and the strengthening of lead by so little as 0·05 per cent of tellurium. Novel combinations of metals led to such remarkable products as the newer permanent magnet steels, containing nickel, aluminium, cobalt and copper, giving such a high concentration of magnetic energy that a bar could be made to float in air in consequence of repulsion by another magnet, and revolutionizing the design of loud-speakers and measuring-instruments. The growing importance of metals of high melting-point, especially tungsten, had led to new techniques, such as 'powder metallurgy', and to the development of the high-frequency induction furnace and of refractory materials far superior to those in general use. Vacuum melting and also the use of exceedingly high pressures would become progressively more important, and called for new materials and new methods of construction.

The substitution of one metal for another, as of a light alloy for steel in the building of ships or bridges, usually involved new problems of design on account of differences in elastic and other properties. Chile saltpetre had been replaced by synthetic nitrogen compounds, and the rapid development of the plastics industry had made possible the replacement of metals for a number of purposes, but such substitutions did not necessarily lessen our dependence on mineral resources. Electric power for nitrate synthesis might be obtained from water, but in some highly industrialized countries had to come from coal, while many of the plastics were derived from coal or petroleum, although, being organic substances, there was always the possibility of preparing them from vegetable sources, for example, through alcohol.

Two papers dealt with sea-water as a source of minerals. Dr. E. F. Armstrong reviewed the problem generally. Salt had long been prepared by the evaporation of sea-water, but more recently the demand for bromine for the manufacture of 'Ethyl' for addition to petrol had led to the recovery of that element, especially in America, where it was blown out of the sea-water by a current of air after displacement by chlorine. Magnesia was recovered in large quantities by precipitation by lime or by calcined dolomite, and the industry had assumed large proportions in Great Britain as well as in the United States. Magnesium, although very abundant in the earth's crust, had only lately assumed great economic importance. It was extracted either by electrolysis of the anhydrous chloride or by thermal reduction of magnesia by calcium carbide, ferro-silicon, or carbon, the last of these presenting special difficulties on account of the high temperature required and the reversibility of the reaction with carbon monoxide.

Since the products of the disintegration of all rocks ultimately reached the sea, most elements must occur in sea-water, although in a state of high dilution. Phosphates, the deposits of which were limited in amount and likely to become exhausted, were wasted in present methods of sewage disposal, Great Britain alone discarding the equivalent of 150,000 tons of rock phosphate a year. Some means might be found of recovering a part of this. Selective absorption of specific elements was now utilized in the various processes depending on base exchange, and a method of recovery of phosphates might possibly be based upon that principle.

Dr. Ernst Bergmann spoke of the Dead Sea, in which the concentration of salts was much higher than in oceanic waters, while the relative proportions of the several elements were very different. The concentration increased from the surface downwards, and for industrial purposes water was taken from the lower levels. At present only potassium chloride and bromine were extracted, Palestine being now the largest producer of bromine, but the high concentration of magnesium salts suggested the use of this source for the production of the metal, provided that electric power were made available. Deposits of phosphates were found on the Transjordanian shore of the Dead Sea.

Means of economizing in the rarer metals used in alloy steels were discussed by Dr. W. H. Hatfield. Since the principal steel-making countries were dependent on imported ores for such metals as tungsten, molybdenum, nickel and vanadium, the conditions of restricted supply in war-time made measures of economy necessary. From May 1940 onwards this problem had been dealt with by a Technical Advisory Committee, and the alloy steels covered by between two and three thousand specifications had been reduced to eighty-five categories, greatly simplifying the choice of steels. It was not always necessary to use the more highly alloyed steels, which could usually be restricted to the heavier masses, for which they were essential to complete hardening.

Another aspect of economy was dealt with by Sir Harold Hartley in a paper on the recovery of metals from scrap. While process scrap, re-used in the plants in which it originated, presented no difficulty, old scrap, from disused or worn-out material, was of a mixed character, and offered many problems of collection and classification. Changes in methods of manufacture and use, such as the repair of parts by welding and improved protection against corrosion, affected the quantities of scrap returning to the furnaces, and the importance of the careful segregation of scrap from alloys containing valuable elements was stressed, as it was by the previous speaker. The great difficulty of securing statistics of scrap and secondary metal was emphasized, the present statistical knowledge of this important question being very unsatisfactory.

The session concluded with a paper by Dr. David Williams on the mineral resources of the Soviet Union. The detailed survey, illustrated by a remarkable series of maps, does not lend itself to abstracting, but both the bulk of the estimated reserves and their wide distribution must have surprised many hearers. Potash salts and phosphates, besides the metallic minerals, were present in very large deposits.

The development of these resources within the last fifteen years had been exceptionally rapid, and although doubt might be expressed as to the validity of some of the Russian estimates of reserves, it should be recalled that there were still vast areas awaiting investigation. Tin and tungsten were deficient, but it seemed likely that the U.S.S.R. would become self-supporting in and even able to export large quantities of coal, iron, petroleum, manganese, platinum, magnesite, phosphates, asbestos, potash and sulphur.

The afternoon session was devoted to economic questions. After the opening address by Sir Stafford Cripps, Prof. J. G. Smith, speaking of international trade in raw materials, said that the arrangement by which certain countries only manufactured goods and exchanged them with other countries producing only raw materials had sometimes been regarded as permanent, but had shown signs of breaking down as old capitalist countries found themselves obliged to extend their agricultural basis, while countries rich in raw materials exported less and worked up more of those materials at home. It was argued that the tendency was for industries to become less dependent on the localization of raw materials, thus admitting considerations other than purely economic ones in the choice of a country's economic policy. The factors were, however, very complex.

Dr. W. A. Lewis, in a striking paper on some aspects of mining finance, confined his remarks in the main to mining in Africa. The ordinary investor regarded mining ventures as highly speculative, owing to the uncertainty of the quantity of ore in a given mine, the fluctuations of price of most metals, and also to the prevalence of fraud. Greater legal control of company promotion would be of service in increasing confidence. The financing of mining had fallen mainly into the hands of large corporations, which could spread the risk and also provide the necessary technical guidance. This 'grouping' system, paralleled by the 'managing agency' system of the Eastern colonies, was good from the investor's point of view, but had the disadvantage that an entire colony might find itself in the hands of one or two corporations, dominated by one or two rich men, since the capital of such corporations came only in small part from the private investor, and mainly from banks and large finance organizations. The Governments of Southern Rhodesia and Tanganyika had set up special funds for financing small mines, which still had a future, and this policy might be extended.

The large corporations, by eliminating competition, were able to make excessive profits, from which the colony derived little benefit. In 1937 the Trinidad mines earned in profits three times what they paid to their native employees in wages, the Gold Coast mines two and a half times, and the Northern Rhodesian mines twenty times, and when dividends of 100 per cent were announced, colonial peoples asked why European capitalists should take out the principal wealth of the country and leave so little. Sooner or later awakening nationalism would compel the colonial peoples to assume control of their own resources, and in the meantime taxation might be increased, or experiments made with joint control, as in the Belgian Congo and Dutch East Indies, where the capital was provided in part by the Government and in part by private enterprise.

Mr. Arthur Notman, taking aluminium as his text, suggested that there was no more fruitful source of international friction than a system of tariffs, exchange controls, and other arbitrary restrictions on freedom of trade. The existence of a great internal free trade market had been an important factor in the prosperity of the United States. Aluminium would play a leading part in the future improvement of communications, and reference was made to a possible policing of the world by an international air force.

The general question of planning and the mineral industries was dealt with by Mr. O. W. Roskill, who concluded that there must be a central international authority which would correlate the plan for the mineral industries with the requirements of other industries, and could be built up out of existing bodies. All nations must be included. Planning of production was meaningless unless accompanied by planning of distribution and consumption. The determination of prices by the free interplay of supply and demand was incompatible with such planning, and it seemed likely that prices would be increasingly related to costs. If such stabilization occurred, producers and manufacturers would not need to protect themselves against fluctuations. Organizations for each group of commodities and manufactured goods would have to control both exports and imports.

The last communication was from Dr. L. Dudley Stamp, who spoke on the exploitation of minerals in relation to national and world planning. It was necessary to distinguish between those minerals which were in limited supply and were removed as completely as possible in mining, such as coal, oil and most metalliferous ores, and those which were so abundant that only parts of the available deposits were likely to be worked, such as limestone, clay, sand and gravel. In international planning it was the first which was important. There was in general a cycle in the development of such deposits—exploration, exploitation and exhaustion. In the early stages there might be a mining boom, with a very rapid development, great increase of population, and sometimes much extravagant building. The period of steady exploitation might be short, as with alluvial gold or tin, or might last a century or more as in a coal-field. Towns might be built and the fact that their prosperity depended on the exploitation of a deposit forgotten. The period of exhaustion could cause great maladjustments and much human suffering. The recognition of the right of the nations of the world to share its mineral resources carried with it an obligation to accept responsibility and to share the burden of such readjustments as might be needed. Examples taken from the British Isles included the decay of the Cornish tin mines, the destruction of vegetation and fisheries by lead mining and smelting, the formation of a stony desert in Northamptonshire after the removal of iron ore from good agricultural land, and the familiar instance of derelict coal-fields. It would appear that mineral exploitation inevitably resulted in a need for restoration, whether of land or of the social structure of the community; that this restoration should be obligatory on those who derived benefit from the working of minerals, and that as the stage of exhaustion was unprofitable, there should be some provision, comparable with an amortization assurance, made while the work was in the flourishing stage.

The Conference closed with the passing of the resolution proposed by Sir Richard Gregory and quoted in the first article (p. 171).

C. H. DESCH.

OBITUARY

Sir William Flinders Petrie, F.R.S., F.B.A.

In NATURE of July 18, p. 84, the respective claims of Sir Flinders Petrie and the late Prof. Reisner to have been the greatest of all Egyptian excavators were here being discussed, and satisfaction was being expressed that the former was still in the land of the living. Now, so shortly afterwards, he has passed from us at the advanced age of eighty-nine, and the mournful duty has arisen of reviewing his achievements and of discussing the influence he exerted upon archæology in England and in the world generally. One outstanding merit must be emphasized at the outset: it would be difficult to recall a life so wholeheartedly devoted to the task its owner set before himself; no hardship, no lack of monetary resources could make him swerve from the purpose he pursued with an energy for which few have the physical endowment, and none could better have deserved the fame and the honours showered upon him, the latter culminating in the knighthood of 1923.

His was a distinctively British career, exhibiting both the strength and the weakness of an intense individualism, enhanced by a private education and (if the truth be told) undisciplined by academic training. All the more brightly shone forth his undoubted genius. Few have possessed so high a degree of flair, or have obtained such accurate results by such unorthodox means. The writer has been told he sometimes made his plans with the help of an old walking-stick, from the original length of which deduction was made for wear and tear. Be this truth or mere fable, certain it is that his plans display a very high degree of accuracy, as was discovered when one of his rivals thought fit to uncover afresh some of the Royal Tombs of the First Dynasty at Abydos, an undertaking which both in its scientific results and in the material finds proved sheer waste of the rival's time.

The trouble is that the cavalier methods Petrie pursued required the hand of the master, and could not so profitably be adopted by pupils. This suggests another point. No one in England has ever excited so much interest in Egyptology, or has introduced so many fresh workers into the field; some of them, like the papyrologists Grenfell and Hunt, were destined to win great fame, while others, as little academically trained as himself, drifted into field work as a sport and drifted out again a few years later.

There was one regrettable side to Petrie's attitude to his science which must not be passed over in silence. No philologist himself, he tended to discount the importance of philology and to foster in his assistants the belief in some sort of antithesis between philology and archæology. This was ill-judged, and resulted in a certain amateurishness with which some of his work, for example, his "History of Egypt", and many articles in his periodical *Ancient Egypt*, is stamped. Obviously the Egyptian archæologist should possess at least a competent acquaintance with the hieroglyphs, just as the most learned decipherer of papyri and inscriptions would be but a poor Egyptologist could he not claim a sufficient working knowledge of archæology. But this having been said, let us hasten to add that almost any defect could be pardoned in one who owned even three quarters of the skill, the devotion and the driving-power of this greatest of all the British excavators.

It has been thought the more excusable here to offer a personal assessment of Petrie's merits since the facts of his career are so well known, have received such wide publicity in the Press, and are also set forth in his "Seventy Years in Archæology" and his much earlier summary "Ten Years' Digging in Egypt" (1892).

For this reason also the rest of this account shall be confined to enumerating the greatest of his discoveries and to stressing the most important of his innovations in archæological method. He had been engaged but four years in the field when, with his work on the Pyramids of Gizah and on the city of Tanis behind him, he started digging on the site of what proved to be the Greek colony of Naucratis (1884). Already he had set new standards in archæology by his attention to the minutest details, by his recognition of the outstanding importance of pottery, and by his personal and sympathetic supervision of his native work-people. His striking presence and personality could not fail to imbue the latter with respect, while at the same time he possessed some of the quick-wittedness with which Kitchener proved more than a match for Oriental cunning.

The work in the Fayyum in 1888–90 brought much fresh knowledge of the Middle Kingdom, but was transcended in importance by the discoveries at El-Amarnah in 1891 and at Nakadah in 1894. On the former site Petrie unearthed the palace of Akhenaten, the heretic king, finding very valuable frescoes and smaller objects, while in the latter he came upon an entirely new culture not at first recognized by him for what it really was, namely, a prehistoric cemetery of vast extent and wealth. In connexion with these prehistoric remains he inaugurated one of his most valuable contributions to archæological method, a classification styled by him "sequence-dating". This consisted in segregating the main groups of pottery, ivory, etc., in superimposed layers, and since no inscriptions were present to supply definite dates, in placing them in sequence with numbers theoretically ranging from 1 upwards, but actually starting at 30 for the oldest known remains, and ending at 80 for the First Dynasty.

As regards the tombs of the Kings of the First Dynasty at Abydos, investigated with great skill and care during 1899–1900, Petrie was not the original discoverer, but the previous excavations by Amelineau had been disgracefully conducted, and Petrie's systematic clearing was salvage of the highest order. A comparatively small dig at Thebes in 1895–96 had brought to light a stela of the reign of Merenptah with the first and only hieroglyphic mention of Israel. In 1911–12 at El-Lahun, Petrie's assistant Brunton came upon a great treasure of Middle Kingdom jewellery, later unfortunately disposed of to New York instead of finding a place, as it should have done, in the British Museum.

The above enumeration of the most outstanding finds shows that it was not given to Petrie to chance upon such sensational discoveries as Carter's tomb of Tutankhamun or Reisner's reburial of Queen Hetepheres. Cumulatively, however, his contribution has been considerably greater, for the number of sites and the variety of the objects found are almost incredible as the outcome of a single lifetime. This inadequate statement would contain an unpardonable omission were not reference made to the constant and unfailing help rendered by Lady Petrie ever since their marriage in 1897.

ALAN H. GARDINER.

NEWS and VIEWS

Imperial Institute of Entomology

In the early part of the century the importance of entomology to the health services and to agriculture in the Overseas Empire was at last beginning to be realized. In 1909 the Entomological Research Committee of the Colonial Office was formed, with Sir Guy Marshall as scientific secretary. In 1913, when the Committee extended its outlook and became the Imperial Bureau, and later the Imperial Institute of Entomology, Sir Guy became director, and he has just retired; he has thus guided the fortunes of entomologists in the Government Services abroad for more than thirty years, ably supported by Dr. S. A. Neave, who has been assistant director since 1913. The period has seen great changes in the position of entomology in the Empire. From a few isolated workers, largely unaware of each other's work, or even of each other's existence, there has developed a small army of several hundred field workers; and much of this progress has been due to the Imperial Institute of Entomology. Instead of being completely out of touch with work elsewhere, the field entomologists have had the invaluable *Review of Applied Entomology*, which has summarized progress in agricultural and medical entomology for the past thirty years. It is difficult to-day to imagine how one got on without this journal.

Another great difficulty of the entomologist abroad was that of getting specimens identified. This problem was one of the first to be tackled by the Bureau, and for many years now the words "kindly identified by the Imperial Institute of Entomology", so frequent in entomological papers from all over the Empire, are a testimony of the great value of this work. No appreciation of the work of the Institute would be complete without mention of the Parasite Laboratory at Farnham Royal, from which useful parasites and predatory insects have been distributed to all parts of the world. Sir Guy Marshall has built up his organization with energy, with vision and with a sympathetic understanding of the difficulties of the man in the field; and now, on his retirement, he hands on the reins of government to his assistant director. Dr. Neave has succeeded to a difficult task in difficult times, but the work he has already done with the *Review*, with the *Zoological Record*, with the "Nomenclator Zoologicus" and in many other ways, leaves no doubt that the Imperial Institute of Entomology is still in capable hands.

Prof. William Peddie

The retirement is announced of Prof. W. Peddie from the Harris chair of physics at University College, Dundee, in the University of St. Andrews. Born in Orkney in 1861, Prof. Peddie was educated in Orkney and Edinburgh, and graduated in that University in mathematics and natural philosophy. A student of Prof. P. G. Tait and a lecturer in the Department of Natural Philosophy, Prof. Peddie obtained the degree of D.Sc. from Edinburgh. He has always taken a keen interest in the work of the Royal Society of Edinburgh, and has served on the Council and as vice-president. In 1907 he was appointed as Harris professor in Dundee in succession to Prof. J. P. Kuenen, the first occupant of the chair, and for thirty-five years has carried on the work of the Department of Physics. In addition to text-books on elementary dynamics and physics he has written works on colour vision (1922) and on molecular magnetism (1929), two subjects on which he has specialized, and he has frequently contributed the results of his work to Nature.

Prof. Peddie reached the conclusion that the Young-Helmholtz theory of colour vision is the simplest, but the mechanism proposed by them is not an essential part of the theory. The formal laws of action, and these alone, constitute the essence of the theory. A paper published in the *Philosophical Magazine* in September 1941 gives a summary of six years' work on magnetization in crystalline media. The results in general sustain Weber's theory, which originated almost a century ago. An appreciative reviewer of his book called the modern presentation "Peddie's theory". The theoretical aspects of physics have always aroused his interest, and in discussing in 1931 the philosophy of "As If" in physical science he wrote: "The idealist, if he is an investigator in physical science, cannot avoid acting upon the postulate of realism. Nothing else gives him a foothold for work. He has to regard the universe 'as if' it were real. All our philosophies are necessarily based upon postulate; all our science is founded upon faith."

Biology and Human Welfare

Speaking at a conference at Newnham College, Cambridge, under the chairmanship of Mr. L. J. F. Brimble on August 8, Sir John Orr outlined his conception of the place of science in the post-war era. Pleading for a clearer vision of the great new world, he said: "What we need to go for in the new world is not the application of physical science for the production of goods to get money-power, but the application of biological science to build better men and a better society." The first step in the new world must be the abolition of poverty, and we must concentrate on building men and women before we build new cities. Sir John expressed the view that the age which is now passing away is largely the age of physical science, with its inventions and discoveries, which have given us power over the forces of Nature. It is to be hoped that when this War is over the age of physical science will be replaced by an age of biological science—the study of life in all its manifestations. Reviewing some of the results of the age of physical science he pointed out that in spite of the new inventions and discoveries the standard of life up to 1840 or 1850 actually fell below what it was before. The reason was that instead of applying the new machines wisely men had applied them to produce goods to sell to get money. "It was not that men were individually bad," he said, "but their whole background was bad. The fundamental ideal of the age was bad and, not only that, men did not even have the vision to see that this system must inevitably collapse, as it did during the War of 1914–1918."

One could have predicted a few years ago that the present War was inevitable. Now it has come it is destroying the age of the application of physical science to the production of money-wealth. Money is losing its power. The age of physical science is being destroyed by the machines which the system itself created. The old ideas are going with it, and to talk of reconstruction in the sense of getting back to 1938 is to talk sheer nonsense. In spite of the fact, however, that they have been driven by the wrong ideal, the people of England are people with an extraordinary sense of justice and kindness. They still retain a grasp on their old religious and ethical ideals. It is because we realize that these ideals cannot exist with the type of world domination sought by Germany that the War is being fought. Sir John emphasized the fact that a first step in the new world must be the abolition of poverty in feeding, clothing and housing, and declared that in the future biological science will be applied much faster than it has been applied in the past. We must concentrate first on building men and women—particularly women. That is more important than building new cities. That can be done by the purposeful teaching of biological science, and if we apply the ideals of biological science in our teaching we shall find we are not very far off the Christian ideal.

Industrial Pest Control Association

A MEETING of representatives of firms in all branches of the industrial pest control industry other than agriculture was held in London on June 9. The firms represented included those interested in natural insecticide raw materials such as Pyrethrum and Derris of Lonchocarpus, manufacturers of basic chemicals such as ethylene oxide and cyanides, manufacturers of speciality products for insect and rodent control, and contracting firms primarily concerned in the application of insecticides, fumigants and rodent killers on industrial premises. After consideration of the growing need for industrial pest control measures, particularly in relation to food storage and the war effort generally, it was unanimously decided to set up a fully representative body to be known as the Industrial Pest Control Association. In the past two months the new Association, with forty members, has set up a strong executive committee consisting of: Mr. C. S. Kroger of W. Edmonds and Co., Ltd. (chairman), Mr. R. G. Berchem of Jeyes Sanitary Compounds Co., Ltd., Mr. F. H. Braybrook of Technical Products, Ltd., Dr. F. P. Coyne of Imperial Chemical Industries, Ltd., Mr. A. F. McIntosh of Thos. Harley, Ltd., Mr. S. F. Sprange of London Fumigation Co., Ltd., Mr. J. B. Wilton of Fumigation Services, Ltd.; Dr. E. Holmes of Plant Protection, Ltd. (hon. secretary). In addition, a small technical sub-committee has been set up, with powers to co-opt other representatives with special knowledge, to advise the Association on technical matters and to collaborate with Government departments and other bodies on matters of mutual interest. Inquiries should be addressed to the honorary secretary of the Association at Jealott's Hill, Bracknell, Berks.

Sir William Tilden, F.R.S. (1842-1926)

SIR WILLIAM AUGUSTUS TILDEN, the centenary of whose birth falls on August 15, is best remembered as an inspiring teacher and for his pioneering work in connexion with scientific teaching in the younger universities of Great Britain. At twenty-two he became a demonstrator in chemistry at the Pharmaceutical Society, at thirty science master at Clifton College, at thirty-six professor of chemistry and metallurgy in Mason College, Birmingham, and at fifty-two he succeeded Sir Edward Thorpe in the chair of chemistry at the Royal College of Science, London. He retired in 1909. Tilden himself wrote some autobiographical notes on his school days and his efforts to qualify as a teacher of science in an article entitled "Progress in Science Teaching", published in the Jubilee issue of NATURE (Nov. 6, 1919); while in his biography of Sir William Ramsay (1918) are to be found accounts of the movement by which Ramsay, Tilden and others in 1889 secured a Government grant of £15,000 for the university colleges of Great Britain. Tilden's books were mainly for the use of teachers and students, but he also wrote some on the history of chemistry. He published some sixty scientific papers. So early as 1884, in his study of the terpenes, he obtained a liquid isoprene which by contact with gaseous hydrochloric acid was partly converted to rubber.

Tilden was president of the Institute of Chemistry during 1891–94 and president of the Chemical Society during 1903–5. He delivered the Bakerian Lecture to the Royal Society in 1900 and eight years later received the Davy Medal. When presented with the Medal he remarked that "In the life of every true scientific man there came sooner of later a time when if he had the smallest amount of success he felt disposed like Archimedes to rush into the street and shout Eureka! Eureka! Those were the moments of real triumph, the moments when one felt that life held something that was very sweet". Tilden, who was born in London and was the son of a Bank of England official, was twice married, and died on December 11, 1926, at Northwood, Middlesex, in his eighty-fourth year.

A Founder of the Royal Horticultural Society

THE Royal Horticultural Society was founded at a meeting on March 7, 1804, at Mr. Hatchard's house in Piccadilly. First among the names of those present was the Right Hon. Charles Greville, whose biography forms the subject of a paper by the present assistant secretary of the Society (*J. Roy. Hort. Soc.*, 67, Pt. 7; July, 1942). Born in 1749, he was a friend of Emma Lyon, later the Lady Hamilton who was associated with Nelson, had a distinguished career in Parliament, built harbour works at Milford Haven, became a fellow of the Royal Society for his work in geology, and practised such wide cultural graces as are denoted by membership of the Society of Dilettanti. Among all this extensive interest he managed to make a specialist contribution to horticulture, being responsible for the introduction of *Lilium concolor*, *Pæonia suffruticosa rosea*, *Camellia japonica*, *Clinogyne dichotoma*, two varieties of Magnolia, and others. Greville's garden near Paddington is said to be the place where American blight first appeared, but its owner overcame this doubtful distinction by suggesting the spraying of fruit trees with lime-wash. The genus Grevillea was named in honour of this horticultural pioneer by Robert Brown.

Prevention of Heart Disease

IN a recent paper (*Bol. Of. San. Panamericana*, 21, 231; 1942), Dr. Hugo J. D'Amato, secretary of the National Department of Hygiene at Buenos Aires, states that diseases of the heart and circulatory system were responsible for 24 per cent of the deaths in Buenos Aires in 1939. A fourfold programme has therefore been devised involving respectively medical prophylaxis and care, influence on specific groups, and economic losses, social assistance and State action. As regards the first point, medical examinations are to be made in such centres as factories, government offices and schools, so that rsons suffering from heart diseases may receive rly treatment. These diseases produce their worst fects during the most productive period (generally ter the age of forty), and it is calculated that 100 illion pesos represents the social cost of early death d forced retirement of such persons. Social assist- ce should be given not only to the actual patients it also to needy persons who are burdened with eir maintenance. As regards State action, the rgentine Government has provided for a compulsory ate examination, and legal restrictions have been ade on the work done by persons suffering from rdio-vascular diseases.

ndocrinology in Montevideo

THE June issue of the *Boletín de la Oficina Sani- ria Panamericana* contains an interesting account the Institute of Endocrinology at Montevideo, hich was founded in 1937 and serves as a teaching, eventive, therapeutical and research centre. It under the direction of Dr. J. C. Mussio Fournier, ofessor of endocrinology in the Montevideo School Medicine, who was recently president of the econd Panamerican Congress of Endocrinology held Montevideo. The Institute possesses a staff of isiting nurses who regularly inspect the schools at ontevideo, and under the guidance of a school octor select for observation and treatment children uffering from endocrine disorders. A hospital is ttached to the Institute, consisting of three wards, r men, women and surgical cases respectively. he majority of the patients are suffering from ndocrine diseases, but other complaints in adults nd children are also treated.

1,000-kw. Wind-driven Electric Generator

A PLANT which is said to represent the first serious ttempt to study the generation of electricity by ind-power on such a scale that its practical and conomic possibilities may be judged, is described in *ngineering* of July 31. The plant consists of a two- laded wind-turbine and a 1,000-kw. alternator ounted on a pintle girder on the top of a lattice teel tower 110 ft. high, and it has been erected on he summit of a 2,000-ft. mountain known as Grand- a's Knob, near Rutland, in the State of Vermont. hough in a sense the plant is experimental, the urrent generated will be used by the Central Vermont ublic Service Corporation. It has been estimated hat it will be possible to use the power of the wind or 4,000 hours a year. The blades of the turbine are ach 65 ft. long and 11 ft. wide and weigh 15,300 lb. he circle described by the ends of the blades is 75 ft. in diameter and at 28·7 r.p.m. the tip speed s 15·785 ft. per minute. The alternator is driven hrough gearing and generates three-phase current t 60 cycles and 2,300 volts. The designer of the ind turbine, Mr. P. C. Putnam, has had the assistance f others, and model tests of his turbine were made n the wind tunnel of Stanford University. There are any interesting features in the plant, and so that n exhaustive study of wind variations can be ade an anemometer tower 180 ft. high has been rected close by and fitted with three types of nemometers.

ecent Earthquakes

THE United States Coast and Geodetic Survey, in o-operation with Science Service and the Jesuit eismological Association, has found the provisional epicentre of the earthquake of June 29, which occurred at about 6h. 26·4m. U.T. From instrumental reports from eleven observatories, the epicentre turned out to be near latitude 34·5° S., longitude 70·5° W., which is south-east of Rancagua in Chile. This is definitely in a seismic district, and the depth of focus of slightly greater than normal is not without precedent near the Andes.

ON August 6 a severe earthquake began recording at 23h. 49m. 04s. U.T. A maximum ground amplitude of 800 μ was recorded at Kew on the vertical component seismograph on August 7 at *ca.* 00h. 25m. U.T. According to a tentative interpretation, the first impulse is a *P* wave, the *S* wave following at 23h. 59m. 15s. U.T on August 6, and according to the tables in use at Kew the epicentral distance would then be approximately 9,000 km.

Announcements

PROF. JAMES GRAY, professor of zoology in the University of Cambridge, and Prof. F. L. Engledow, Drapers professor of agriculture in the University of Cambridge, have been appointed members of the Agricultural Research Council in succession to Sir Merrik Burrell and Prof. D. M. S. Watson, whose terms of office as members of the Council have expired.

PRESIDENT ROOSEVELT has appointed the following committee to examine the whole field of synthetic rubber production and to report as quickly as possible: Mr. Bernard Baruch (chairman), who was the head of the War Industries Board during 1917–18; Dr. James Conant, president of Harvard University, and Dr. Karl Compton, president of the Massachusetts Institute of Technology.

A PANEL has been set up to inquire into the possibility of improving the ventilation of tanks either by use of refrigeration or by air conditioning. It is constituted as follows: Mr. S. A. Wood, senior scientific officer, Scientific Research Department, Ministry of Supply; Dr. Dorey, chief engineer surveyor, Lloyd's Register; and Dr. Ezer Griffiths, principal scientific officer, Physics Department, National Physical Laboratory.

THE Honorary Medal of the Royal College of Surgeons of England has been awarded to Lord Nuffield in recognition of his conspicuous service in assisting the improvement of natural knowledge and of the healing art and of his many liberal acts and distinguished labours inspired by the desire to advance the science and practice of medicine and surgery. The Honorary Medal was instituted a hundred and forty years ago, and this is the nineteenth occasion on which it has been awarded.

THE following appointments, promotions and transfers in the Colonial Service have recently been made: D. E. MacGregor, veterinary officer, Nigeria; F. Davidson, rubber production officer, Gold Coast; C. W. Lynn (agricultural superintendent), senior agricultural superintendent, Gold Coast; J. D. Kennedy (senior assistant conservator, of forests), conservator of forests, Nigeria; C. R. Petty (senior surveyor), deputy director of surveys, Gold Coast; H. R. Binns (veterinary research officer), senior veterinary research officer, Palestine.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Onset of Reproductive Phase in Grasses and Cereals

In the Gramineæ inflorescence production commences suddenly: the new primordia arising at the apex remain small but their axillary buds appear precociously and rapidly begin to develop into spikelets or groups of spikelets, according to the species. The abruptness with which vegetative growth changes over to inflorescence production suggests that there is a sort of minimum condition in the internal economy of the shoot apex which must be reached, and that once the point of balance is passed the vegetative type of growth ceases. The obvious suggestion is that the onset of the reproductive phase only occurs when a certain carbohydrate/nitrogen (C/N) ratio is reached. If this is the case, it should be possible to alter markedly the number of leaves produced before inflorescence production by altering the nutriment in which the plants are growing. Purvis[1], however, has shown that the amount of nitrogen supplied to rye seedlings has little effect. Plants grown under long days (16 hours) and manured with a full culture solution and 1/10 *N* culture solution produced 13·3 and 12·4 leaves respectively if germinated at 1° C. and 21 and 20·59 leaves respectively if germinated at 18° C.

I thought that the successive removal of the laminæ as they appeared might either lower the C/N ratio in the plant by cutting down the photosynthesis, or at least greatly lower the amount of food available for transport to the apex, using the term 'food' in its widest sense. It was thought that, as a consequence, the seedling might have to produce an increased number of leaves before inflorescence production commenced. As a test, grains from a single head of a pure line of wheat, *Triticum vulgare* var. *ferrugineum* Al. 'April Bearded', were sown in a large pot of good garden soil in mid-January in a cool greenhouse. (Thanks are due to Prof. Percival for original material from which the line was derived.) As the plants grew, those on one side of the pot had each successive lamina removed just above the ligular region immediately it was fully exposed. These plants could thus only photosynthesize by each developing lamina and by the sheaths left on the plant. As would be expected, the experimental plants were much smaller than the controls, as shown in the photograph taken on May 3, when most of the plants were gathered.

Although the two sets of plants differ so markedly in size, it will be seen from the results tabled below that the removal of the laminæ does not greatly influence the number of leaves produced before inflorescence initiation commences. Furthermore, if anything, removal of the laminæ slightly reduces the number of leaves rather than increasing them as was expected. The treated plants grew more slowly, and when collected, about a fortnight before the controls would have headed, were even then about three weeks behind. The reduction in the number of spikelets from 22 to 13–14 is clearly another indication of the starvation of the plants. It may be that this last effect is not merely due to a reduction in carbohydrate production, but at least partly to a decrease in the amino compounds available to the apex from the leaves. It may easily be that the removal of the leaves has not altered the C/N ratio of the apex itself but only reduced the amount of food present.

		Number of		Highest internode with basal	
		Vegetative leaves	Spikelets	Bud	Root initials
Control	1	12	21	8	8
	2	12	22	8	8
	3	12	22	8	8
	4	12	23	8	8
Average ..		12	22	8	8
Laminæ removed	1	11	12	7	6
	2	11	13	–	–
	3	11	14	8	8
	4	12	14	9	8
	5	12	15	8	8
Average ..		11·4	13·6	8	7·5

From these results, in conjunction with the observations quoted from Purvis[1], it would seem that it is impossible to make much alteration in the number of leaves which must be produced at the apex of a growing cereal like rye or wheat, either by altering the amount of nitrogen supplied to its roots or by greatly reducing its photosynthesis by the removal of large areas of assimilating tissue.

The stability of the leaf number at maturity in spite of drastic treatment is also apparent in Nutman's[2] study of plants grown from dwarf embryos of rye, where grains weighing only 2·3 mgm., obtained by early harvesting of the heads, gave plants with about the same final number of leaves as those grown from normal grains (about 36 mgm.).

Workers investigating the biology of cereals and grasses might well use the number of leaves on the main stem as an index of the maturity of the individual at any stage, since it seems to be more or less independent of maltreatment suffered by the plant.

Relative Toxicity of Insecticides

The mode of action of insecticides is still very obscure, and it often happens that their relative toxicity is largely dependent on the method of testing employed. Consequently it is difficult to compare the results of one worker with those of another.

Carefully planned standard methods are necessary, and we welcome the publication by Dr. Parkin of the technique adopted by the Pest Infestation Laboratory of the Department of Scientific and Industrial Research[1].

One point, however, might be criticized: it would seem unwise to rely on only one species of test insect. I have found that the relative resistance of insect species changes very much with different types of poison[2]. Therefore any one insect may not give a true indication of the effectiveness of a new insecticide.

In the Pest Control Laboratories of Messrs. Imperial Chemical Industries the difficulty is met by testing new samples on several pest species. Some interesting results emerged from testing even well-known poisons with a range of insects. Table 1 shows the relative toxicity to seven insect types of a variety of fumigants and vapour poisons.

TABLE 1. RELATIVE RESISTANCE OF PEST INSECTS*

Species	Stage	Median lethal dose (mgm. litre)											
		5 hr. exposure at 20° C.									1 hr. 25° C.		1 hr. 20° C.
		Benzene	Toluene	Trichlorethylene	Perchlorethylene	Carbon tetrachloride	Chloroform	Methyl acetate	Ethyl acetate	Ammonia	Hydrogen cyanide	Ethylene oxide	Sulphur dioxide
Ephestia kühniella	Pupa	243	>Sat.	299	>Sat.	>Sat.	387	—	—	—	1·6	37	—
Calandra granaria	Adult	213	90	251	101	592	359	70	99	8·9	22	17	10
Calandra oryzæ	Adult	183	76	219	90	473	254	38	36	7·3	24	12	31
Ephestia kühniella	Larva	152	62	204	91	448	255	44	50	7·7	0·4	26	16
Tineola bisselliella	Larva	137	55	176	86	352	215	—	69	—	6·5	18	24
Tribolium castaneum	Adult	64	33	103	50	137	181	65	68	5·9	0·6	41	17
Cimex lectularius	Adult	62	25	67	42	113	106	16	25	12	0·14	26	6·7
		Group 1						2		3			

*Experiments done in Pest Control Laboratories, I.C.I. Ltd. in 1939.

When this table is examined it is seen that the insects show the same order of resistance towards the various fat-solvent vapours (Group 1) but entirely different orders to the gaseous fumigants (Group 3). The explanation seems to be that an order of resistance is characteristic of a type of toxic action. The action of the fat-solvent vapours is mainly physical, whereas the highly toxic fumigants like cyanide undergo specific chemical reaction in the tissues. The two esters in group 2 would be expected to act like group 1 but are likely to be more readily hydrolysed in the tissues. It is interesting to find that the order of resistance to asphyxiation by carbon dioxide is the same as that towards the fat-solvent vapours (Table 2). (The exposures were made in glass phials, flushed through with carbon dioxide from a cylinder for five minutes and then sealed.)

TABLE 2. RESISTANCE TO ASPHYXIATION BY CARBON DIOXIDE

Species	Stage	Median lethal exposure (hr.)
Calandra granaria	Adult	213
Calandra oryzæ	Adult	68
Ephestia kühniella	Larva	54
Tribolium castaneum	Adult	30
Cimex lectularius	Adult	15

Returning to the general point, we see that *Tribolium castaneum* (Dr. Parkin's test insect) is relatively susceptible to the fat-solvent vapours and to hydrogen cyanide. But it is highly resistant to ethylene oxide, which would not appear to be a very promising fumigant judged by this species only. On the other hand ethylene oxide is more toxic to the *Calandra* spp. than hydrogen cyanide.

Contact poisons show the same specificity as fumigants. Thus, it has been shown that the house-fly[3] and the Aphids *Rhopalosiphum pseudobrassicæ*, *Aphis spiræcola*[4], *A. pomi* and *A. sorbi*[5] are more resistant to pyrethrins than to rotenone; while the reverse is true for the honey bee[5], the beetles *Epilachna corrupta* and *Diabrotica duodecimpunctata*[4] and the tick *Ornithodorus moubata*[6].

If the insecticides to be tested are merely pyrethrum solutions of different strengths, it is satisfactory to rely on one species, carefully reared as Dr. Parkin specifies. But if toxic principles other than pyrethrum are to be investigated, it would seem advisable to use more than one test species.

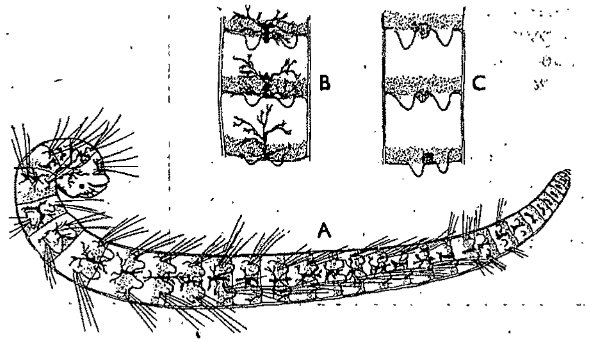
Stellate Chromatophore in the Polychæta

THE stellate chromatophore has been chiefly studied in the Crustacea and Vertebrata, to which groups it was supposed at one time to be confined[1]. It is, however, present in leeches[2,3,4,5] and has been proved experimentally to contract in the dark and expand in the light. The purpose of this note is to show that the stellate chromatophore also occurs in polychæte larvæ. It may have an extensive distribution in the annelid phylum.

On the suggestion of Mr. G. P. Wells, who has kindly helped with this note and supplied details of literature, I made rough experiments at Plymouth with the larvæ of *Pœcilochætus serpens* Allen, which possesses stellate chromatophores noted first by Dr. E. J. Allen[6].

Structures resembling the vertebrate stellate chromatophore in appearance occur in many, but not all, polychæte larvæ. Wilson[7] found, in Polydora larvæ, that the chromatophores were sometimes expanded and sometimes contracted, but he made no experiments to determine the cause of pigment migration.



A. Pœcilochætus larva, 1·5 mm. long, from plankton, Plymouth Sound. Alive.
B. Chromatophores of same enlarged.
C. Chromatophores of another specimen kept in dark overnight.

I have been able to show that, in Pœcilochætus larvæ and in the larvæ of an unidentified Spionid, the chromatophores, which normally are expanded in the light, can be made to contract by keeping in darkness.

The worms taken direct from the plankton samples and showing branching chromatophores were kept in a cupboard in a finger bowl overnight. The next morning they were quite active and their chromatophores were contracted. The chromatophores appear to show "primary reactivity" of Hogben and Slome[8], as those of leeches do[5]. The worms were fixed in picric and mounted in euparol. The pigment in the chromatophores is almost black and shows no sign of dissolving in the permanent preparation. It is probably melanin.

Tracing Plane Spiral Coiling

Lieut. A. T. J. Dollar's letter on optical projection as an aid in studying plane spiral coiling of small fossil lamellibranchs[1] prompts me to point out a variation in technique which in the investigation of brachiopods gave superior results.

The study of a number of Lower Carboniferous brachiopods has forcibly suggested that the median or venter profile of the ventral valve is so constant as to be diagnostic of a given species. In arriving at this conclusion many accurately drawn venter profiles were compared. In the case of *Airtonia hudsoni* Cope[2], experiment on various methods of obtaining profiles, including that described by Lieut. Dollar, was made. The most satisfactory method was found in the use of an enlarging camera. The brachiopod valve was placed with the venter profile parallel to the surface of the bench, being held in position with a small block of 'Plasticine'. By careful adjustment on the vertical racking, a sharp image was obtained upon the ground-glass focusing screen of the camera. A small sheet of tracing-paper was secured in position in apposition with the screen and the venter profile traced with a pencil. Best results were obtained in a dark room using artificial illumination. Comparison of profiles was facilitated by having a separate small sheet of tracing-paper for each individual. The profile of the holotype for any given species was traced in coloured ink and taken as the standard profile.

By this method the position of the umbo can always be marked. Employment of the technique described by Lieut. Dollar frequently means that this important character is lost in the body of the silhouette.

In dealing with massive brachiopod valves such as those of *Daviesiella llangollensis* (Dav.), a different technique, which can be used when a laboratory is not at hand, was adopted[3]. An optical method could not be employed owing to the presence in many specimens of a ventral sinus. A piece of fairly stout lead-covered cable was obtained, the wire core with its cotton and rubber covering was withdrawn, and the lead tube slightly flattened. A mark near one end of the tube was brought into juxtaposition with the tip of the umbo of the brachiopod valve. The tube was then bent around the venter, care being taken that it was in contact with the valve throughout its length; the anterior margin of the valve was indicated by the production of a sharp bend. The curve so produced was laid upon tracing-paper and secured firmly on a drawing-board. A pencil line was then drawn along the inner periphery of the curve.

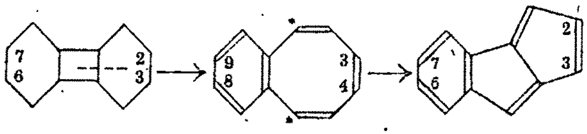
Structure of 'Diphenylene'

The preparation of diphenylene (I) by the action of sodium on 2 : 2′-dibromodiphenyl was described in 1911[1], but later workers have been unable to confirm this claim[2]. W. C. Lothrop[3] has recently described a different compound, $C_{12}H_8$, m.p. 110°, believed to be diphenylene (I), prepared by distilling either 2 : 2′-dibromodiphenyl, or, better, diphenylene-2 : 2′-iodonium iodide, $\{C_{12}H_8I\}$ I, with cuprous oxide. By the latter reaction he also prepared 2 : 7- and 3 : 6-dimethyldiphenylenes and found that the two products were identical; this was accepted as proof of the symmetrical structure (I).

The highly strained diphenylene molecule (I) is unlikely to exist, and consideration of the most probable course of the synthetical process employed by Lothrop leads to the conclusion that 'diphenylene' is the comparatively strainless tricyclic compound (III). The removal of the two halogen atoms will first give a diphenyl with free valencies in positions 2 and 2′. On the natural assumption that these valencies can only unite with simultaneous rupture of the potential *cyclo*butadiene ring (*cyclo*butadiene does not exist), see (I), the result will be to give a diradical of benzo-*cyclo*-octatetraene (II) (trivalent C atoms marked with *), which will rearrange into the least strained structure (III). This view of the structure of 'diphenylene' is in harmony with the identity of the two dimethyl derivatives, since both isomeric dimethyl-diphenylene-iodonium iodides must yield the same intermediate, the 4 : 8-(3 : 9)-dimethyl derivative of (II), and, therefore, the same final product, which may be either the 2 : 7- or the 3 : 6-dimethyl derivative of (III).



(I) (II) (III)

The preparation of 'diphenylene' by Lothrop's method has been confirmed. Catalytic reduction results in absorption of nearly three molecules of hydrogen, and thus it does not readily yield diphenyl as (I) would be expected to do. Moreover, it does not show the properties of an acetylene or an allene.

'Diphenylene' is the first known derivative of the partially aromatic system consisting of two fused 5-membered rings possessing four double bonds, a system first postulated by J. W. Armit and R. Robinson[4], and the preparation of which was attempted by J. W. Barratt and R. P. Linstead[5]. The double bonds in formulæ (II) and (III) are not fixed, and three uncharged forms of (III) may be written.

A full account of this work will be published elsewhere.

Simplification of Musical Notation

As a result of a mess argument, in which two music lovers protested that the existing system of notation is too complicated, I endeavoured to produce a simpler method. The result was a 12-note arrangement instead of the customary 8-note one; therefore it would require 1½ times the space, using six lines per octave and a thick line for each *C*. The scale of *C* is shown, the arrow indicating the key note. In addition to doing away with sharps, flats and key signatures, when this method is used for keyboard instruments, the music is read in exactly the same way for both hands.

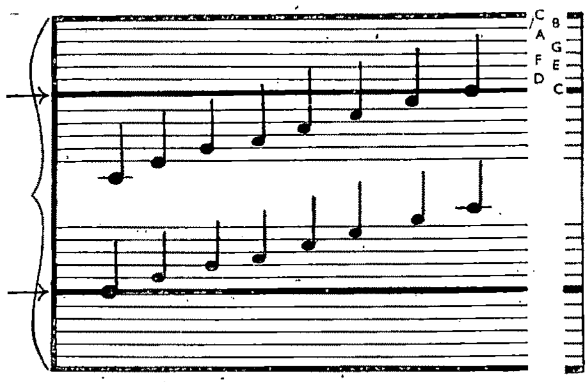
I see no reason why this system should not be applicable to all other instruments and lead to the abolition of special clefs for the instruments of the orchestra.

Some days later, I saw the interesting letters from Mr. Ll. S. Lloyd and Mr. K. B. Wood in NATURE of June 6, p. 640.

Like all readers of music, Mr. Lloyd reads a group of notes, not each individual note; this facility has been acquired by practice and experience. But what about the beginner? Which is the easier to grasp and eventually to understand and read—the 8-note plus accidentals method, or the plain 12-note method.

Mr. Wood's spacing takes even more room, but is splendid for keyboard use. I wonder if that can be dispensed with so as to make the system universal for all instruments.

Finally, I should like to point out, in defence of the extra lines required, the great steps that have been taken since plainsong was written on four lines. The extra line, sharps, flats and all the rest were added to the existing system, until it emerged in its present form. For equally tempered instruments we have had a 12-note scale for two centuries. For such free instruments as the violin and even the voice, the adjustment of each individual note depends entirely on the player or singer, who plays or sings to the pattern of the music, adjusting the pitch as dictated by his own ear. He could read this pattern from a 12-note stave and produce the key as harmonically correct as he could from the 8-note stave.



ALAN G. SMALLEY.

Preparation of Deoxycholic Acid

THE problem of obtaining deoxycholic acid (3, 12-dihydroxy cholanic acid) in quantity has been rendered acute by present conditions, implying the closure of the sources (largely German) of pure bile acids. Isolation from bile is laborious and yields are uncertain. Since the acid is now widely used in bacteriological media, its preparation from cholic acid (itself easily obtained from bile) has been successfully undertaken. Cholic acid (3, 7, 12-trihydroxy cholanic acid) has been directly oxidized by chromium trioxide under controlled conditions to a mixture giving the semicarbazone (m.p. 250°) of 7-keto, 3, 12-dihydroxy cholanic acid in approximately 45 per cent yield. Reduction of this substance gives a 70 per cent yield of deoxycholic acid of high purity, identified by chemical and physical properties and oxidized to the well-known dehydrodeoxycholic acid (3, 12-diketo cholanic acid).

THE ROYAL OBSERVATORY, GREENWICH

THIS year's Report of the Astronomer Royal refers to the work of the Royal Observatory during the period May 1, 1941–April 30, 1942. London suffered few air attacks during this time, and no further damage to the Observatory has occurred. Daylight observing is still carried on at Greenwich, but the larger instruments will, of course, remain dismantled for the duration of the War.

The public time service continues to function from two out-stations, each maintaining, in case of breakdown at the other, a complete time service involving transit observations, clock maintenance, and transmission of time signals to the Post Office and the B.B.C. The Rugby vernier signals, which are the precision British time signals, have up to the present normally been transmitted from Station *B*, since the clocks at station *A* are mounted in temporary fashion and suffer from serious mutual interference. During the year, however, the three free-pendulum clocks and a quartz clock at station *A* have been remounted in a specially constructed building, and it is hoped that their behaviour will now be sufficiently improved to allow this station to share regularly in the transmission of the rhythmic signals. The published corrections to the Rugby signals and to foreign signals are now based on some or all of nine clocks—seven Shortt clocks and two quartz oscillators—mounted in various parts of the country. By working on a "mean clock" and by making certain changes in the routine of signal transmission, a distinct advance has been made in the precision of the Rugby signals, the value of which as a day-to-day frequency standard has thereby been increased. Accurate allowance for land-line lag is now made before each signal is transmitted. Comparison of the signals against the clocks, or of one clock against another, is now facilitated by the use of thermionic panel units which eliminate the variation of lag inevitable with mechanical relays. Intercomparison of the clocks has shown that in the matter of small erratic changes of rate even the best free-pendulum clocks are inferior to quartz clocks.

The Chronometer Depot has settled down into its new quarters, and repair, rating and issue of chronometers and watches to the Royal Navy have continued without interruption. A vibration machine constructed in the Observatory workshop has been brought into use for testing aircraft watches under service conditions. Tests of the effect of magnetic fields of strengths up to 8·5 gauss on the rates of chronometers and watches have been instituted, no doubt with war conditions in mind, and are now nearing completion.

The last report of the Observatory stated that work with the Airy transit circle had been terminated after ninety years continuous observation. Since then, news has been received of the destruction of Poulkovo Observatory during the bombardment of Leningrad. This will be such a serious loss to fundamental positional astronomy that observations are to be resumed with the old Greenwich instrument on a restricted programme, including particularly transits of the sun. Minor damage to the housing of the instrument has therefore been made good, the instrument has been overhauled, and work will be resumed shortly. Analysis of previous observations with this instrument arranged according to wind direction shows that declinations south of the zenith are measured larger by about $0{\cdot}10''$ when the wind is north-east than when it is south-west. The observations of latitude variation had already given a similar result. This agreement shows the advisability in positional astronomy of applying locally determined latitude variations so as to eliminate spurious annual terms due to systematic seasonal fluctuations in wind direction. The division errors of the fixed circle of the new reversible transit instrument show on analysis a cyclic error, recurrent every $2\frac{1}{2}°$, which may reach $0{\cdot}19''$; thus emphasizing the need of determining the division error of each graduation.

The photoheliograph observations show that the expected decline in solar activity continues, though there have been four notable periods of resuscitated activity. Of the four big spot groups the area of which exceeded 1,000 millionths of the hemisphere, two exhibited bright eruptions in Hα light which were later followed by great magnetic storms on the earth. Assuming that the magnetic storms were caused by solar corpuscles emitted at the time of maximum intensity of the chromospheric eruptions, the mean time of travel of the particles is calculated as 20 hours.

The Nautical Almanac Office continues its essential work. Last year's report referred to the destruction by fire of the type and plates for most of its publications: during the early part of the year under review printing delays due to this circumstance and to a change of printing contract caused a dangerous accumulation of arrears. The Nautical Almanac for 1942 was in fact not published until November 3, less than two months before the date to which it refers, but the arrears are being wiped off so satisfactorily that the 1943 edition appeared on April 3. The failure of communications with many of the other ephemeris offices has led to a small increase of computational work; but duplication is avoided so far as possible by interchanging information with such of the offices as are still free to collaborate. The War has hastened a decision which would have been reached in any event, namely, to abandon the indiscriminate provision of occultation reduction elements. The observations for 1938 and 1939 show that the majority of the computed reduction elements are never in fact used, owing to the particular occultation not being observed; and of the remainder most are used once only. In future the Office will do the individual reductions for all observations actually made, provided that observers will do that portion of the reduction depending solely on their position and that of the star. A revision of the Air Almanac has recently been planned in conjunction with the Air Ministry: the effect will be to redistribute the data on the two pages allotted to each day, one of which now becomes a "night" page and the other a "day" page. The change should result in greater simplicity in use, at the expense of a slightly larger page. The present R.A.F. Star Charts are based on a recent investigation carried out by the Office on the optimum method of identification of the stars used in aerial navigation.

The Magnetic Department of the Observatory, in addition to the regular daily observations of the magnetic elements, is at present engaged in preparing charts for the Admiralty showing the iso-magnetic lines in declination, horizontal intensity, inclination and vertical intensity. The declination charts, of which the previous edition was published in 1937, are now ready; those for *H* and dip, for which the previous editions are dated 1922, are well advanced. Vertical-intensity charts are a novelty.

Features of the year's weather observed at Greenwich include a very wet August (4·146 in.) followed by an unprecedented lack of rain in September and October, during which only 1·41 in. fell. The winter was conspicuous for cloudiness, the sunshine recorded being only 55 per cent of the average, and for consistently low temperatures in January and especially in February, which had a record number of days twenty-six) on which temperatures below freezing were recorded.

Visitors to Greenwich Park will miss the famous 24-hour clock dial at the shattered main gates of the Observatory, and the daily fall of the time ball; but the familiar domes are still there, though somewhat perforated, and the Wren building still stands guard over the all too characteristic bend in the river. Meanwhile, as the familiar, never-failing "six-pips" testify, the work of the Royal Observatory goes on.

RELICT VEGETATION OF THE SHILLONG PLATEAU, ASSAM

AN account has been given by Dr. N. L. Bor, forest research botanist at the Dehra Dun Institute (*Ind. For. Rec.*, vol. 3, No. 6, Govt. of India Press, New Delhi, 1942), of the vegetation of the Shillong plateau. The broad divisions are evergreen forest, pine forest and grassland. The status of each type is discussed. An analysis of the evergreen species in three widely separated groves shows that floristically they are related. The conclusion reached is that the climax is the evergreen forest, while the pine forest and the grassland are seral in status. This is a bald summary by the author; for there is much that is fascinating, and some important lessons to be learnt from the record.

Shillong, the summer capital of the Province, is situated in the Khasi and Jaintia Hills district. The portion here dealt with is the elevated tableland stretching from Cherrapunji, reputed the rainiest pot in the world (900 in. have fallen in a single year), in the south to Shillong in the north; it consists of a wide plateau of rolling downs intersected here and there with narrow gorges and some 4,000–,400 ft. in elevation, the latter near Shillong.

The three great divisions of the vegetation are grassland, pine forest and evergreen forest, and here as in so many other parts of the world their disribution or survival has been due to man and his actions. Thirty years ago, the *Imperial Gazeteer of India* stated of the Khasi and Jaintia Hills: "At an elevation of 3,000 ft. the indigenous pine (*Pinus Khasya*) predominates over all other vegetation and forms almost pure pine forests. The highest peaks are clothed with clumps of oak, chestnut, magnolia, beech and other trees, which superstition has preserved from the wood-cutter". Both Hooker, 1849 "Himalayan Journals") and Griffith (1837) recorded heir impressions of the scenery, and both were truck with the bareness of the country, the great xpanse of grassland on the rolling downs. Bor tates that after the lapse of a century they have very much the same appearance to-day. The clumps of evergreen forest mentioned in the *Gazeteer* of thirty years ago also still exist, solely because they are regarded as sacred. Hooker has recorded that the flora of the Shillong plateau, in comparison with the area it occupies, is probably richer in the number of flowering plants than any other area similar in size in the whole of Asia.

The inhabitants of the plateau are of Mongolian stock and have maintained themselves intact for many centuries. By nature and practice they are shifting cultivators, termed Jhuming in Assam and Bengal. All the hill tribes in Assam live in this way, the most wasteful of all forms of cultivation. As Bor correctly points out, in the distant past when populations were small and forest areas extensive, little harm was done, but he writes: "it is a very different tale when the cultivators live in stationary settlements and their numbers continue to increase. What one may call 'saturation point' has now been reached by most of the hill tribes and one of their most urgent problems is that of the exhausted soil which must produce more at more frequent intervals. Some tribes solve this question by having permanent fields which they can irrigate, others manure their fields, while the Khasis go to the trouble of growing forests [of pine] which can be cut down and the area occupied by them cultivated".

Since the evergreen groves are sacred, it is the pine forest areas which are selected for cultivation. It is impossible to follow the author in his interesting descriptions of the methods used; he mentions that the introduction of the potato in 1830 has greatly increased the pine forest cultivation. Immigration by Nepali graziers, encouraged by the chiefs for the revenue they bring, has taken place for many years past and the graziers, says Bor, "are undoubtedly responsible for the devastation of forest over very large areas. In areas which were covered with forest a century ago, nothing but grassland remains, and on the whole it is very poor grassland. This grassland is composed of rather coarse species and it is fired by the graziers as soon as it is dry enough in order to obtain the new flush, which is eaten by cattle. Under treatment of this kind grassland degenerates rapidly and loss of soil by erosion is very considerable". This might equally be written of Africa.

From the forest-botanical point of view the interesting part of Bor's paper is his investigations into the evergreen forest or groves. It is stated that the pagan Khasi regards these groves as the abode of his tribal gods and is forbidden by tribal custom to fell, lop or damage a tree in any way; no flower may be plucked, no fires lit, no cattle grazed. He believes that the deity inhabiting the grove deals out punishment to those who break the tribal custom in this respect. This punishment is usually sudden death. Bor expresses the fear that with the conversion work of the missionaries—he might have added the inevitable arrival of Western civilization, so-called—there will result the loss of tribal veneration for the sacred groves, which will then fall to the evils of the axe, fire and so forth; a regrettable loss of what in his opinion are the remnants of the former forest which spread over much of the region. For Bor's reasons the paper must be consulted, but he shows quite definitely that the climate of the region is a 'forest' one as opposed to a 'grass' one. But surely it should not be beyond the power of a present-day administration to protect by other means what the uncivilized tribesman has for so long safely protected, even when that strict guardianship was due to what the Western peoples regard as purely pagan faith. A study of the depreciated grassland and pine forest areas sufficiently indicate how strict for a long period of time this careful protection has proved; nor should it be beyond the powers of the Indian sylviculturist to extend the areas still occupied by this old indigenous evergreen forest.

Bor's investigations, as he says, are by no means complete; they "represent the gatherings of one rainy season in Shillong on the few occasions when holidays or Sundays afforded a release from the pressure of other work. Great as is the similarity of the floristic of the three areas based on these collections, it is believed that further work will make the similarity even closer". The tallest trees, says the author, in these dark and gloomy evergreen woods, are perhaps 60 ft. tall. The dominant stems have smooth, cylindrical boles and thick crowns which touch. The trunks and branches of the trees on the margins are loaded with lichens, mosses, orchids and other epiphytes. A small-tree layer can at times be distinguished, but it is not at all distinct. The shrubby and herbaceous layers are in places well marked and in others almost non-existent. The soil is covered with mosses and Selaginellas and is deeply stained with humus. Whenever a gap occurs in the canopy owing to the disappearance of a giant, natural regeneration of the dominant species is satisfactory. In his list of species, Bor enumerates 32 canopy trees, 66 small trees, 80 shrubs, 120 herbs, 30 ferns, 20 grasses and sedges, 8 parasites and 44 climbers, which endorses Hooker's remark on the richness of the flora of the region.

The author writes: "It is realized that a far larger number of the groves would have to be examined before reliable details of fidelity and constancy for the species could be obtained, but the object of this paper is not a statistical examination of the groves but an inquiry into the ecological status of the groves based upon the available data".

MANUFACTURE OF OPTICAL GLASS

THE production of optical glass is one of the most difficult as well as one of the most interesting of manufacturing processes. Fraunhofer was the first to realize the necessity for improvement in the manufacture of glass in order to bring it to the necessary degree of homogeneity and to make it free from internal strain, essential requirements for optical glass. It may be said that it has taken more than a hundred and fifty years to bring the art of optical glass manufacture to its present state. Messrs. Chance Bros. have been engaged on the task for nearly a hundred and twenty years and the Chance-Parsons optical glass embodies their experience, together with the newer research work in their laboratories as well as that of the firm owned by the late Sir Charles Parsons, under whom notable advances were made.

It is a cause for satisfaction to record the high quality of the glass produced by a British firm, even under war conditions. In homogeneity and freedom from strain and mechanical defects, Chance-Parsons optical glass can compare favourably with that of any other maker. The publication by Messrs. Chance-Parsons of a new catalogue of optical glass is thus something of an event for the optical designer and manufacturer, as well as for the physicist, as here is found exact data about glass for condensers, ophthalmic lenses, optical instruments and colour filters.

To measure the advance in the last thirty years it may be recalled that on the outbreak of the War of 1914–18 the British maker listed some dozen types of glass with refractive indexes given for four lines of the spectrum from *C* to *G′*. Now there are nearly one hundred types, and the data cover nine lines fairly evenly spaced over the visual spectrum from helium *b* to mercury *h*. Refractometry in the infra-red and the ultra-violet is still in the laboratory stage. When it is recalled that the same state of affairs existed with respect to the measurements in the visual spectrum until Abbe introduced exact measurements and published the data in a manufacturer's catalogue, it is possible to hope that an extension of the data to include the infra-red and ultra-violet will be a possibility before long. This would be a really useful advance as these regions are becoming of increasing importance in industry as well as in pure science. At present, when information is wanted as to the refractive indexes of any glass in the invisible regions, resort must be had to the inaccurate methods of extrapolation, or to the laboratory.

An innovation in the present catalogue is the introduction of a new system of classifying glasses in order of their stability, based on a thermodyne test devised by Chance Bros. which is said to conform well to the results of atmospheric action. Stability is assessed in terms of the period of time during which the glass may reasonably be expected to show no signs of surface tarnish. It is to be hoped that this classification will in time be extended to all the glasses on the list.

A useful feature of the catalogue is the distinguishing, by heavy type, of those glasses which are made regularly and so can be supplied with a minimum of delay. Furthermore, particular care is paid to the maintenance of a stock of certain glasses which are in very general demand, and these are indicated by an asterisk. These can be repeated, in successive melts, within very close limits of optical properties. The designer and manufacturer are therefore advised to use these wherever possible as a change to a new melt can be looked forward to without misgiving, calling for minimum alteration of the data of the system.

There are no fresh glasses recorded in the present catalogue nor any having the extreme properties claimed recently in patent literature, yet the range is wide and covers the normal requirements of the optician; British optical instrument manufacturers have no cause to complain of the lack of variety of material offered them.

Considerable advance is to be noted in the section relating to colour filters, which should be of particular value in laboratory work and in colorimetry, which is becoming of increasing industrial importance.

Glass filters naturally have not so wide a range as those made from coloured gelatin but have certain advantages. They are usually more stable; are more robust and can be more easily handled in the unprepared state; are cheaper when required to be of optical quality since the working of only one parallel flat is involved instead of two; for the same reason they can be made thinner and lighter; and they have a certain adaptability as the transmission can be varied by suitable choice of thickness.

The filters now offered provide a range of colours from infra-red to ultra-violet, as well as neutral and heat absorbing glass. There is also one (didymium) showing sharp absorption in a narrow region in the neighbourhood of the *D* line.

Transmission curves are given for each glass on a separate chart. This supersedes the previous method of plotting densities and is in conformity with other makers' lists. The integrated visible transmission, for a standard lamp and thickness of filter, is also supplied, and a formula given by which the transmission can be calculated for any other thickness. It is believed that there are only two other makers of coloured glass of optical quality in the world, and the English list compares favourably in range with any other.

The makers are to be congratulated on the publication of the new catalogue under present conditions.

H. W. LEE.

MOTION AND FORMATION OF THE PLANETS

TWO papers under the title "Gravitational Theory of Planetary Rotation", and "A New Theory of Planetary Formation", by J. Miller, have just appeared (*J. Brit. Astro. Assoc.*, 52, 5 and 6, June and July 1942). Miller shows that a spherical body or a loose agglomeration of particles, held together by gravitational force or cohesion, which is describing an orbit around a central body, will acquire a rotation in a sense opposite to that of revolution. This rotation is produced by the unequal attractions of the central body or centre of force on the near and remote sides of the smaller body, and the axis of rotation will be perpendicular to the orbital plane. The linear velocity of rotation will vary as the diameter of the body, and will also be a function of the distance between the body and the central force. Owing to the fact that a second order term appears in certain computations, the linear velocity will not be exactly proportional to the diameter, and in addition, internal friction between the different strata has an important effect.

A relation between increments of time in rotation rates and increments in diameters is deduced by Miller, and the theoretical times of rotation for the different planets are computed. Some of these agree well with the actual times of rotation, and, where discrepancies occur, it is suggested that the internal frictions of the planets, for which it is difficult to calculate exact figures, are responsible. It is assumed that the solar system once revolved around the centre of a star cluster, which, in turn, was revolving around the centre of the galaxy, and planetary rotations originated as a result of the difference in the attractions on the near and remote sides of the planets, to which reference has already been made. These rotations have been maintained since they were established, though, as pointed out, there were probably other disturbing factors which modified the original rates to a small extent.

No explanation is given in the first paper of planetary formation, but this problem is attacked in the second paper. The sun alone in the solar system is first dealt with, and it is conceived as originally describing an orbit around a centre of force which may be, as in the previous case, a stellar cluster or the galaxy. Under favourable conditions, such as approach to the periphery of the cluster, the disruptive force of the latter, due to its differential attraction, will at a certain stage overcome the combined forces of the sun's gravitational pull on its external layers and of the cohesion of the particles. A portion of the sun will be removed, and as it makes closer approaches to the cluster, more material will be torn off. Miller suggests that the outer planets were removed first, and as the disrupted sun moved closer to the cluster, it lost more and more material which formed the remaining planets, Pluto being the first to be removed at a great distance and Mercury the last when the sun was nearest to the centre of attraction.

The theory differs from the planetesimal hypothesis of Chamberlin and Moulton in many ways. A cluster, not another star, is held to be responsible for the disruption. In addition, internal forces in the sun, caused by the high temperature, are not considered necessary to assist with the ejection of matter. A tentative explanation of Bode's Law is given, but this is not worked out in detail. The physical condition of the sun at the time of the formation of the planets is left an open question; it may have been in a state somewhat resembling its present condition, or it may have been in a semi-nebulous state. It is assumed that the matter composing the superficial layers did not all possess the same cohesive force, from which it may be inferred that the sun was not entirely nebulous at the time of the disruption, though it may have been very much more extended than it is at present. Miller's theory requires that the outer planets, which were first disrupted, should possess less cohesion than those closer to the sun, so that the cohesive power should increase from Mercury outwards. As, however, great changes have taken place in the planets since their formation, this rule cannot be applied very strictly.

INDIAN FORESTRY RESEARCH*

AS a record of useful economic activities, a report entitled "Forest Research in India and Burma, 1940–41" is an encouraging summary of many-sided investigations under difficult conditions. It deals with the work of the Forest Research Institute at Dehra Dun during the period under review. Naturally the outstanding feature of the year's activities has been the influence of the War. At first the demands made upon the staff of the Institute were connected with supplies, but as its work is primarily research it was for this reason capable of dealing only with comparatively small quantities of materials. It became, therefore, wisely agreed that the Institute could not make its best war contribution by turning itself into a supply unit. It has confined its programme in consequence to research work in connexion with various war problems.

While the activities of the Utilisation Branch of the Research Institute were largely engaged upon war work, rather than normal programmes, those of the Botanical and Sylvicultural Branches were more especially engaged on the normal research and other duties where interruption would lead to waste of previous efforts. In the Utilisation Branch many inquiries were dealt with in connexion with timbers for various war uses. These included bamboos for aircraft work and tent poles; timbers for rifle parts and tool handles; containers for ammunition, for packing army boots, etc. As an example it may be mentioned that cases for army boots were generally made of wood of the chir pine from the Himalayas. The enormous demand created by the War made it necessary to consider other timbers. Semul timber was suggested by the Ordnance Department. Comparative tests of both chir and semul boxes were made and tests showed that the semul boxes were practically as strong as chir boxes and possessed in addition certain advantages. It appeared that the original design of the boxes could be greatly improved so as to produce a much stronger box by very small additions costing not more than a few annas per box. Boxes embodying the improvements suggested were, therefore, made and tested. They proved to be fifteen times stronger than boxes made according to the original design. Among other work of this branch has been the testing of various woods and bamboo for mechanical pulp for newsprint-quality papers. Five species were found suitable for this purpose and inquiries are going on as to supplies and whether they are accessibly situated so as to make the matter an economic proposition.

---

* Forest Research in India and Burma, 1940–41. Part 1: The Forest Research Institute. Pp. 161. (Manager of Publications, Delhi, 1941.) Rs. 1.12 or 2*s*. 6*d*.

In the Chemical Branch much attention has been given to chir pine tar, which has been successfully modified to suit requirements of large consumers such as rope works and rubber companies. The cutting off of imported supplies of wood tar has also led to a heavy demand for wood creosote, and other by-products, on the Medical Department. Large-scale production of these has now been arranged and it is computed that the sale of these by-products will bring down the cost of production of heavy tar by about 20–25 per cent. Another problem of interest, but of a much smaller nature, has been the provision of prepared wood dust used by makers of dry electric cells to incorporate with inorganic oxide to give the necessary porosity. Hitherto this substance was imported from Germany, but a highly satisfactory substitute appears to have been obtained by mixtures of spruce and bombax sawdust. It is hoped that in future it will no longer be necessary to import this material.

The Entomological Branch has been occupied with the importation of the bug *Teleonemia scruplosa* from Australia as an aid in the extermination of the pest-plant Lantana. Trials have been successful, but the insect has not so far been released in the field in case, having destroyed lantana, it should attack teak, which belongs to the same natural order of plants. It is not considered likely that such an event would happen, but nevertheless the eventuality is not being overlooked. Problems created by the emergency exploitation of the wood of *Boswellia serrata* for hutting and packing-case timber have been explored, and more especially the best procedure for protection against boring insects of several kinds.

A notable feature stressed in the report is the importance of the results obtained by the Botanical and especially the Sylvicultural Branches in the past. These have made possible the economic exploitation of the immense Indian timber supplies with the least damage to their future continuity.

FORTHCOMING EVENTS

Sunday, August 16

Association of Scientific Workers (at the Institution of Mechanical Engineers, Storey's Gate, Westminster, London, S.W.1), at 3 p.m.—Conference on "The Scientific Film and Scientific Film Societies".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Mathematics—The Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham (August 24).

Borough Electrical Engineer and Manager—The Town Clerk, Municipal Offices, Cheltenham (endorsed 'Borough Electrical Engineer and Manager') (August 28).

Graduate Teacher of Mechanical Engineering in the West Hartlepool Technical College—The Chief Education Officer, Education Committee, West Hartlepool (August 28).

Principal of the South Dorset Technical College, Weymouth—The Acting County Education Officer, Education Department, Shire Hall, Colliton Park, Dorchester (August 31).

Regius Professor of Engineering at Edinburgh University—The Private Secretary, Scottish Office, Fieldon House, 10 Great College Street, London, S.W.1 (September 7).

Head of the Chemistry Department—The Principal and Clerk to the Governing Body, Wigan and District Mining and Technical College, Wigan (September 12).

Harris Chair of Physics, University College, Dundee—The Secretary, The University, St. Andrews (December 31).

Assistant Lecturer in Zoology—The Registrar, University College, Exeter.

Graduate Teacher of Chemistry in the Smethwick Junior Technical School—The Chief Education Officer, Education Offices, 215 High Street, Smethwick 41.

Lecturer in Civil and Mechanical Engineering—The Secretary, Woolwich Polytechnic, Woolwich, London, S.E.18.

FOOD STORAGE AND TRANSPORT

THE problems of storage and transport of food have troubled men ever since they began to crowd into cities and to attempt to live at any density in northern latitudes. A diet of the cereals that made these developments possible is obviously monotonous ; less obviously, but as inevitably, it is inadequate to maintain health. The three chief deficiency diseases that are recorded as causes of deaths—scurvy, beriberi and pellagra—are associated with diets consisting too exclusively of the three great cereals—wheat, rice and maize. In England scurvy was common until the introduction of potatoes and root crops, which supply vitamin C directly to human beings, or feed animals that will provide fresh meat and milk.

War brings back the old problem in an acute form. Armies are transported to places where they cannot get fresh food, and civil communities are cut off from their normal supplies. During the War of 1914–18, in spite of the relatively high standard of nutrition maintained and the recognition of the relation of these diseases to diet, British troops in Mesopotamia suffered from scurvy and beriberi, and small epidemics of scurvy appeared in Britain when potatoes were scarce in 1917. When the diet is uniform and monotonous the effects of any deficiency become cumulative ; hence the frequency of beriberi in prisons and asylums. Soldiers and others who live on fixed rations, if these are not soundly planned, are liable to deficiency diseases ; while civilians, though their food supply may be less well cared for, escape because they get a greater variety of diet and may protect their health by what may appear to be extravagances and indiscretions. The rations of British troops[1] in the Mediterranean in 1915, and even the diets of Armenian refugees at Port Said[2] in 1916, would have seemed luxurious to German civilians in 1917 ; but the soldiers got beriberi and the refugees pellagra, while the Germans suffered from neither.

The more the exigencies of war limit our food supply the more should we aim at maintaining a variety of foodstuffs and insist that these should keep their full nutritive value. We should not depend on supplements of vitamins. The diets given to British soldiers in the Mediterranean area during the 1914–18 period were planned on the basis of knowledge as it had stood a few years before; but they proved deficient. It would be presumptuous to assume that we now know the whole range of our nutritive requirements and that a diet made up artificially, on the basis of knowledge as it stands now, would be complete. We must still depend on natural foodstuffs for our nourishment and use vitamin supplements only as a last resource.

Two vitamins, obviously, need to be considered—A and C ; for the supply of vitamin A is reduced by the loss of imports of butter (33 per cent of the supply in 1938 came from areas now in enemy hands) and that of vitamin C by the restriction of the imports of citrus fruits. We depend mainly on vegetables to make up the lack of these two vitamins. In the early months of the year, when green vegetables are scarce, supplies of both fall below the amounts considered necessary. Preserved vegetables would help us to tide over this period. Soldiers who have to depend on food transported from a distance are liable to go short of vitamin C at all times of the year, and they may get little vitamin A from sources such as butter; preserved vegetables that retain their vitamins are therefore a necessary part of their rations. Apart from these more obvious examples, the supplies of nicotinic acid, riboflavin and animal protein are reduced by the shortage of meat. We should, therefore, aim at conserving these two vitamins and the biological value of proteins in any foods that are preserved.

The conditions of the present War modify the problem; they enhance the importance of transport as compared with storage. Owing to difficulties of shipping, weight and bulk must be kept to a minimum. So far as the supplies of the people of Great Britain are concerned, one solution is to limit imports to foods, such as wheat, that contain little water, and to produce the perishable foods at home. But this does not solve the problem of the soldier abroad, who depends on shipping for the whole of his rations. However, half or more of the weight of most of the perishable foods is made up of water. If this could be removed the tonnage required for their transport would be correspondingly reduced. We need, therefore, a method by which foodstuffs can be dried, without loss of their nutritive properties, rather than preserved in other ways such as canning.

Attempts have been made, from the earliest times, to preserve the perishable foods, more in order to provide variety than to safeguard health; but these attempts were not wholly successful; the products were not even palatable. In England the stored meat became high during the winter; strong spices were needed to mask the taste and prodigious quantities of beer to wash down the spices. The vicious tradition of strong sauces and pickles and the less noxious habit of copious beer drinking had once their justification. During those phases in the history of scurvy in which the relation of the disease to lack of fresh fruits and vegetables has been accepted, efforts have been made to prepare dried vegetables for use as antiscorbutics. During the War of 1914–18 the only vegetables in the rations of the Austrian army were dried by a process in which an influential personage had an interest. They were popularly known as "barbed wire"; the discontent caused by these bad rations contributed much to the collapse of the Austrian army. All attempts at the preservation of fresh vegetables failed for reasons that we now understand. The processes of canning fruits, by which some of the vitamin C is preserved, were developed in order to provide variety; the improvements of the commercial processes, which ensure that very little of the vitamin C is destroyed, have been dictated more by the desire to preserve the flavour than by any thought of nutritive value.

The present need to economize shipping has stimulated new efforts to preserve foods by drying without loss of palatability and nutritive value. The methods have made use of recent discoveries in connexion with the loss of vitamin C in cooking. Until a few years ago, it was thought that the vitamin C in vegetables is destroyed rapidly when these are heated in presence of air, in the same way as it is in simple solutions. It was therefore natural to suppose that the best way of drying vegetables would be to freeze them and then evaporate water under reduced pressure. The product obtained by this method is bulky, and owing to its open structure very susceptible to the water vapour of the atmosphere. It is now realized that the ascorbic acid is more stable when in plant tissues; but that an enzyme present in the cells destroys the ascorbic acid when the tissues are damaged by bruising or by heat. The main lossess in cooking are due to three processes: first, the action of the enzyme during the period that elapses after the heat damages the cells and before it destroys the enzyme itself; second, the extraction of the ascorbic acid by the water in which the vegetable is cooked; and third, and least important, destruction by heat and oxidation, without the assistance of the enzyme, as in simple solutions. Losses in cooking can be reduced to a minimum by heating up the vegetable rapidly to boiling point, in order to give the enzyme little time to act, and by using cooking water repeatedly so that the concentration of ascorbic acid in it approaches that in juices of vegetables. In the same way, the losses in drying are due to the action of the enzyme.

The extent to which modern knowledge has been foreshadowed in the past is remarkable. For not only had the essential role of fresh fruit and vegetables for the prevention of scurvy been demonstrated and forgotten repeatedly up to 1916, but so far back as 1757 Lind wrote that when the Lords of the Admiralty proposed that dried vegetables should be tried as antiscorbutics "it was objected by the very ingenious physician [Dr. Cockburn] that no moisture whatever could replace the natural juices of the plant lost by evaporation and, as he imagined *altered by a fermentation that they underwent in drying*". Change "fermentation" to "enzyme action" and the words of the very ingenious physician might be written to-day.

If vegetables are first scalded rapidly, the enzyme is destroyed and they can then be dried in a current of air, without special precautions save that the temperature should not rise above 80° C. Vegetables dried in this way and later cooked contain as much ascorbic acid as do cooked fresh vegetables. Loss of carotene (which is the precursor of vitamin A) can be avoided. Meat treated by preliminary short cooking loses none of its nicotinic acid and riboflavin. From the point of view of nutritive value the difficulties of drying have been overcome. Yet people will not eat foods, however great their nutritive value, if they are not as palatable and attractive in appearance as those with which they are familiar. Many families in Great Britain have gone short of animal protein this year, although they could get unlimited supplies of skim milk powder. Fortunately, palatability and appearance seem to run parallel with nutritive properties. The preserved vegetables are eaten as readily as fresh, and dehydrated meat will serve one of its most important functions in modern diets—that of providing flavour. As ascorbic acid can be estimated without difficulty, it should be possible to guarantee the general qualities of dried vegetables by insisting that they should contain specified amounts of ascorbic acid. The new method is commonly called dehydration to distinguish it from the old drying processes in which nutritive value was lost.

It is probable that the drying plant in Great Britain, in the immediate future, will be no more than sufficient to meet the needs of troops. It is to be hoped that, at some time in the future, it will be possible to use dried vegetables to add to the civilian supply of vitamins C and A during the early months of the year. The process seems so simple that it should be possible to make an efficient domestic dryer. Storage in air-tight receptacles should not be necessary, as the dried vegetables keep their ascorbic acid for some months when exposed to air.

After the armistice of 1918, the great shortage of shipping and the crippled state of the railway systems of Europe hampered and delayed the relief of the urgent scarcity of food east of the Rhine. When hostilities again cease, the available shipping will again be insufficient, the railway systems more severely damaged and the need for food will be even more serious. The difficulties of transport are recognized as one of the obstacles to the relief of famine. The diets recommended by the Health Organization of the League of Nations[3] for famine relief are made up of dry foods, cereals, milk powder and cod liver oil; they do not provide vitamin C. Dehydrated foods should be most valuable in supplying a more satisfactory diet.

When the urgent demands of famine relief have been met, a new problem will arise if our promises are taken seriously. We have guaranteed that no one in any part of the world shall suffer from want. It should be comparatively easy to ensure that no people go in want of food energy. In peace-time there is no gross shortage of food energy, when crops are normal, in any part of the world. An International Famine Prevention (not Relief) Organization could keep a watch on crops throughout the world and keep a stock of cereals that could be shipped to any area where a bad crop was anticipated. But it is perishable foods which are scarce. The best final solution would be that some of these perishable foods should be produced in countries which are specially suitable, and transported to other parts of the world, while a considerable proportion should be produced where consumed. This local production is both convenient and economical, as one-type agriculture is in the long run unsound. But it involves the reorganization of agriculture and a redistribution of the population of the most congested areas.

This will all take time, and in the interval these perishable foods must be imported from other countries in some form suitable for transport; again, dehydration should lessen the difficulties of the task. The production of the quantities of those foods that will be required will involve an enormous expansion of plant, and this expansion will raise problems of materials and labour, which will have to be apportioned between these and other projects. This process of reconstruction will involve a gigantic co-ordinated scheme, and it will come to nothing if it is not thought out beforehand. No speeches, declarations or charters will, by themselves, make the fruits of the earth fall into the lap of the Indian coolie or even of the peasant of south-eastern Europe.

MAN'S RELATION TO THE LIVING WORLD

The Discipline of Peace

By K. E. Barlow. Pp. 214. (London: Faber and Faber, Ltd., 1942.) 8*s.* 6*d.* net.

THIS stimulating little volume makes an admirable complement to Lewis Mumford's "Technics and Civilization", which contains indeed the essence of Dr. Barlow's argument. Whereas Mumford is concerned primarily with the effect of the machine on man and how man is to regain control over mechanization, Dr. Barlow's approach is from the biological side, and he is concerned with the effect of man's interference with the balance of Nature. The importance of these ecological considerations, alike for our war effort and for post-war reconstruction, is slowly being realized, and Dr. Barlow's volume should materially assist that process of education.

The main argument of the book is that since man lives by the living balance of Nature—soil, plant and animal woven together in a vast balanced system—it is important that man should ascertain how his own character is related to the rest of life and how his machines link up with it. Only against this background can our essential social problems be understood. Justice and the association of man with his fellows in a commonwealth of peace are only possible when an attempt is made to administer the commonwealth of mankind for the benefit of mankind. If man is to enjoy the fruits of his estate, he must first recognize what is due to the natural world by which he lives, and become the responsible manager and administrator of Nature and no longer the mere exploiter.

It is one of the tragedies of the present situation that just when the ecological argument which Dr. Barlow ably sustains in his chapter on soil erosion is becoming more widely appreciated, the exigencies of total warfare are leading to further exploitation of natural resources and disturbances of the balance of Nature on a scale and in terms of a short-range policy, which it may take the work of generations to repair. On the other hand, as Dr. Barlow points out, the change back from war economy to peace economy fortunately involves an inevitable reorganization of industry which may well give us the opportunity to strike a new balance between industry and agriculture, though it would be rash to assume that the implications of the reactions of food, flood and agriculture are as yet fully or widely grasped. That is an essential preliminary to the development of the adequate organization, and the recognition in a number of recent reports on reconstruction of the importance of a balanced relation between agriculture and industry is at least a hopeful sign.

The value of Dr. Barlow's volume at the present time lies also, however, in his lucid exposition of what is involved in any policy or programme for reconstruction. He brings us face to face with the permanent conditions of politics—the laws of the relation of man to his environment which political philosophy and social planning have tended to ignore. Man's first peace problem is to secure the conditions which will make it possible for him to live at all, and one of the first aims of a wise peace conference would be the restriction of the trade of agricultural peoples to the limits imposed by the balance of Nature, even although this involves a change in the social organization. The idea that agricultural practice must be increasingly modified by the need for protecting soil and vegetation is forced on us not merely by considerations of town planning or location, but also by the primary instinct for survival.

Granted that man must increasingly co-operate with, instead of exploiting, Nature, and that the prospects of peace depend ultimately upon human understanding and effort and sufficient humility and determination to work tolerantly with the processes from which our well-being derives, something approaching a revolution in thought will be required before the great industrial nations will accept not merely the discipline of personal behaviour but also the shrinkage in industrial activity involved in the organization of a new economy in which industry is no longer an orgy of exploitation but a limited and balanced organ in the kingdom of life. Dr. Barlow's exposition of what is involved in regard to international trade between industrial and agricultural communities should bring home to every reader how far we yet are from being able to attempt to lay down the blue prints of a new order which could claim to be durable.

This realistic approach is not Dr. Barlow's only claim upon the attention of the scientific worker. In his argument he links together the ideas of discipline and peace—so often mistakenly regarded as opposed —and brings us to face the imperative necessity for a faith or philosophy for living. Discipline has too long been despised as a military or slave virtue, and the fact that it is one of the fundamental virtues, close to the core of Christianity itself, without which civilization cannot survive, is commonly forgotten or ignored. Even Prof. Mannheim eschews the word in calling for the elaboration of a new and dynamic conception of both freedom and discipline in social reconstruction.

There are healthy signs in the growing recognition that there must be civic duties and responsibilities as a counterpart to freedoms and rights in a new order, that the emphasis must be on service owed to the State rather than on rights conferred. Dr. Barlow's description of discipline in what may be termed the professional or scholarly sense of the word, the self-restraint and conformity which must be accepted by any disciple or recruit in a skilled or learned occupation, cannot but induce the reflection that we have yet much to learn before we acquire the technique and discipline essential to the building of an ordered world, dynamic not static, and free from the strains set up by lack of balance or disequilibria. In Dr. Barlow's view, the higher social and political activities of man are a further elaboration of the processes in Nature in which, as we pass from plant to animal and to man, the characteristic discipline of each is elaborated and interwoven with the disciplines which preceded it, and their understanding is equally relevant to the problem of providing in human society the conditions of peace.

In his attempt to point the way to an adequate philosophy, Dr. Barlow is less successful than in his ecological analysis, but none the less his book is a fine challenge to the fundamental thinking that must precede any real reconstruction. The absence of such a philosophy is largely responsible for unco-ordinated, destructive and unsatisfying energies. If man with his formidable powers wishes to live at peace in the world, it is essential that his knowledge should be an adequate guide for his acts, and nothing but positive articles of faith will be of value to us. Our task is to understand how conflict between man's initiative and that of Nature can arise: on this question of the relation of knowledge and action, Dr. Barlow's point of view is suggestive and to many scientific workers, if not novel, at least unusual. Modern activity is based on science, but pointing out that science, which is merely the elaboration of a faculty which man has always possessed even if in rudimentary form, should not be blamed alone because man interferes with the detail of his surroundings without heeding the archetypal pattern into which that with which he interferes is gathered, Dr. Barlow insists that what is new in the scientific civilization is the complete separation of the manipulative from everything else, including the archetypal organization of Nature. While greatly increasing the scope of the manipulative technique of science and extending the range of man's own physiological performance, this has also released manipulation from the major discipline of Nature.

To strike a balance between these major disciplines of life—that of Nature on one hand and of man and of his manipulations on the other: is one of the major problems to be solved if man is to regain control of the machine which is the immediate social consequence of his use of science. A new conception of machine organization is a first preliminary to a stable world order. The over-riding prerogative of the machine must be replaced by a balance and an integration with the other factors in the biological hierarchy, in which not merely the physical and physiological needs of man but also his cultural, social and spiritual needs are satisfied.

Dr. Barlow does not conceal the difficulties which will be encountered in the practical application of the ideas for which he argues so cogently. The co-ordination of our machines with the other phases of natural and social life, for example, is an urgent aspect of replanning our cities. On the other hand, he makes equally plain the dangers to essential liberties inherent in present attempts to make man's actions fit an industrial system instead of allowing him to recognize his natural relationship and the importance of reconciling the discipline which is necessary to society with the preservation of the qualities of the citizens who come under that discipline.

The book is a courageous attempt to see life steadily and to see it whole, and to envisage the action which must follow as we come to understand the discipline under which we must live. Here is no flinching from consequences but a challenge to both thought and action. The price of liberty in a social system is the display by the management of the community of the powers of combination and order which are characteristic of life. Man's freedom to understand his situation must be absolute, but the primary issue is not how we are to treat materials but how men are to treat each other and the life of the earth which endows them. To realize the full potentialities of an ordered freedom within the delicate structure of life, we must first create within the wide estate of Nature the conditions which that freedom implies and demands. Whether or not we agree with all Dr. Barlow's conclusions, no one can question the sincerity or the dignity of this call to the fundamental and creative thinking on the adventures of ideas out of which alone we can hope to build a social and an industrial order which will serve man's twin desires for order and for growth.

R. BRIGHTMAN.

BIOLOGY OF THE CUCKOO

Cuckoo Problems

By E. C. Stuart Baker. Pp. xvi+207+12 plates. (London: H. F. and G. Witherby, Ltd., 1942.) 25*s.* net.

THIS is the most exhaustive work on the biology of the cuckoo that has yet appeared. The author's qualifications for writing it are unique, for not only has he studied the habits and economy of birds of this family for nearly seventy years, but also he has obtained far and away the most complete collection of cuckoos' eggs, together with the eggs of their fosterers, that has ever been got together, for practically all the known genera, species and races of Europe and Asia are represented, besides some from other countries. Moreover, the work of other investigators is not neglected in discussing the various problems dealt with in this book.

The first part deals with the necessity for cuckoos' eggs being adapted to those of their fosterers. Mr. Baker's evidence clearly shows that the owners of the selected nests often display discrimination, for they may either desert the nest in which the cuckoo's egg has been deposited, or they may eject the egg or in some other way destroy it and so prevent it being hatched. Such discrimination has resulted in the evolution of adaptation between the eggs of the cuckoo and those of their fosterers in size, colour and general appearance. Since individual cuckoos normally keep to the same foster parent, there comes to be a close resemblance between the eggs of the parasite and those of the dupe. Thus, the case would appear to be one of simple Darwinian selection. The evidence for all this is very fully set out, not only for the common cuckoo, but also for other species and varieties of Cuculidæ, and Sir Edward Poulton in a foreword fully endorses Mr. Baker's conclusion. The beautiful coloured plates which are reproduced from Miss Edna Bunyard's original drawings showing the types of eggs of various kinds of cuckoos, together with the eggs of their respective fosterers, add to the value of the treatise.

In the last chapter dealing with adaptation, the author discusses the origin of the parasitism, and points out that the habit of laying eggs without nests was probably primitive in birds, being normal in their reptilian ancestors. Hence the practice of so many cuckoos may be regarded as being partly of the nature of a reversion to a state when birds laid their eggs in various places without making nests.

The next part of the book deals with the question as to how the cuckoo deposits its egg in the fosterer's nest. The author accepts Chance's evidence as proving beyond contention that cuckoos very usually lay their eggs in open nests, as do so many other birds, but without the cuckoo placing its feet and weight upon the other eggs. In other cases, however (as with some cuckoos in India), the eggs may be projected into nests within holes which the cuckoo cannot enter. Further, in addition to these two proved methods, the author thinks that there is a third way whereby eggs are placed in nests in which they can be neither laid nor projected, and he discusses the evidence for the old assertion that the bird may lay its egg on the ground and then carry it in its beak. Without coming to any definite conclusion, Mr. Baker is of opinion that this method is adopted in cases where the bird could not insert its egg in any other way. This probably happens sometimes with the plaintive cuckoos of India and with some other species.

The last part of the book treats of other cuckoo problems such as territories, the ejection of fosterer's eggs and young, numbers of eggs and provision of nests before laying, and the evidence in all these matters is fully given. The author states that with all the species of Cuculus the eggs are laid at intervals of forty-eight hours, once the process has started. The number of eggs is usually from twelve to eighteen. It is very unlikely that the eggs are fertilized in the ovaries, as the author appears to assume, for the observations of Warren and Kilpatrick clearly indicate, as pointed out by Hartman and Hammond, that in the fowl the gametes unite at the anterior end of the oviduct. In the turkey and various other birds (and possibly in most or even in all) the eggs of the entire clutch are fertilized as a result of one treading, so that the spermatozoa must survive for twenty to thirty days within the body of the hen. In gallinaceous birds, however, ovulation takes place spontaneously, whereas for most other birds there is general evidence that the first ovulation does not occur without coition, or in any event without a stimulus from the male, and further, that the process in nearly all birds depends also upon the number of eggs in the nest, since it may be repeated many times if the eggs be removed. One would like to know if similar considerations apply to the cuckoo. The observations indicating that cuckoos are promiscuous suggest that they copulate several times during the short single breeding season. One would like to ascertain if the oviduct normally contains living spermatozoa through the whole period. The existence of suitable nests within the territory may well constitute the main stimulus for repeated ovulation. Assuming this to be so, when the cuckoo lays in the nest of an unsuitable fosterer such as the wren, or outside its territory, it is probably because the bird has already ovulated as a result of an earlier stimulus, and holds in the oviduct an egg that must pass out. The absence of available nests would presumably inhibit ovulation but not the actual laying, once the egg has left the ovary.

The book concludes with valuable appendixes containing data of the weights and measurements of eggs, dates of laying, desertion and rejection of eggs and various other interesting matters. It may profitably be studied in conjunction with Friedmann's book on the cowbirds and Davis's article on the American cuckoos of the sub-family Crotophaginæ, recently published in the *Quarterly Review of Biology*, in which similar problems are discussed. It is to be hoped that a new edition will be provided with an index.

F. H. A. MARSHALL.

Genetics for Medical Students

By E. B. Ford. Pp. iv+162. (London: Methuen and Co., Ltd., 1942.) 7*s.* 6*d.* net.

THE publication of this competently written book which was prepared ostensibly for medical students is particularly opportune. In a straightforward and clear manner the author outlines the principles of particulate inheritance. The medical reader will be pleased to note that examples from man replace bottled Drosophila or wrinkled peas. After an adequate and clever account of Mendelism, which may surprise a pedantic geneticist, of linkage and the genetics of sex, there is a chapter on mutations and the nature of heredity. This chapter is a brilliant essay which will go far to counteract prevalent fallacies regarding the inheritance of environmentally influenced characters.

Other chapters on polymorphism, blending inheritance, gene action and blood groups answer many problems of the medical and sociological worker. The author suggests a useful nomenclature to clear up the muddle apparent in most accounts of the genetics of blood groups.

A chapter is devoted to methods which may be adopted in analysing the inheritance of characters in man. There are useful appendixes containing references for further reading, a list of inherited characters in man, and an account of mitosis and meiosis more than adequate for the comprehension of modern genetics.

This book fills a long-felt want by the medical profession and contains both simple descriptions of the fundamental principles of human genetics and illuminating passages of considerable thought and originality.

F. W. Sansome.

The Statesman's Year-Book

Statistical and Historical Annual of the States of the World for the Year 1942. Edited by Dr. M. Epstein. Seventy-ninth annual publication, revised after Official Returns. Pp. xxxvii+1474. (London: Macmillan and Co., Ltd., 1942.) 30*s.* net.

THE revision of statistical information for many States of the world has been difficult and in some cases impossible, but nevertheless this annual volume contains all the latest figures for the British Commonwealth, the United States and other lands within reach, while for enemy lands, or enemy-occupied lands, figures are at least up to the date of enemy action and even later. The editor has retained the arrangement of States as in pre-war editions except that Estonia, Latvia and Lithuania are now included with Soviet territory. Abyssinia tardily remains within the pages of Italian colonies; Syria remains under French tutelage; but the position of States matters little; the factual information is the valuable side of the book.

It has been found impossible to include the usual tables of world production of various commodities, but two maps, as usual, are provided, one showing naval bases in the Indian and Pacific Oceans and the other the boundary settlement of this year between Ecuador and Peru. Under additions and corrections there have been inserted many facts about Canberra, the federal territory of Australia, and about recent social and economic changes in the authoritarian regime in France. The size of the volume is practically the same as in recent years.

The Philosophy of Edmund Husserl

The Origin and Development of his Phenomenology. By E. Parl Welch. Pp. xxiv+337. (New York: Columbia University Press; London: Oxford University Press, 1941.) 22*s.*

EDMUND HUSSERL died in 1938 at the age of seventy-nine. His writings have had considerable influence on the Continent, but not much in English-speaking countries. He was mainly concerned to give an adequate account of the nature of experience, as that behind which we cannot go and upon which all belief and action are founded. Husserl considered experience to be self-revealing, so that careful attention to what is present to the mind is all that is needed and indeed possible; provided that experience is understood in its full sense, as that which is lived through and directed towards something, not taken partially and incompletely as a collection of 'sense data' after the manner of the Positivists. Like many thinkers, especially German ones, Husserl, having got hold of one good idea, runs it to death by expecting it to do the work of a whole philosophical system. He seems to have thought he was rescuing philosophy from a false psychology, but it is possible that his real merit has been to inspire the Gestalt School of thinkers to help to rescue psychology from a false philosophy. In this matter, however, it is doubtful whether Husserl's attempt at a comprehensive system has done more than the tentative efforts of his teacher Brentano.

The author of this book has tried conscientiously to expound Husserl's thought in clear and intelligible English, and also to compare it with some other types of philosophy. He has supplied an extensive bibliography and some useful criticism of other thinkers, but, for the rest, Husserl remains obscure and only partly intelligible. The fault does not appear to lie with the expositor.

A. D. R.

Electrical Engineering

By W. Tolmé Maccall. Vol. 2. Pp. viii+463 (London: University Tutorial Press, Ltd., 1942.) 15*s.*

THIS book, combined with vol. 1, "is intended to cover the fundamentals of all branches of electrical engineering dealt with in the usual three years day courses". The intention is an ambitious one, and, while the book compares very favourably with others of a like nature, it is not surprising that the result is a superficial treatment of doubtful value to the serious student. It is to be hoped that the average undergraduate is given a deeper insight into the fundamentals of the subject than is provided by the author. The book could have been improved considerably in this respect by the exclusion of those topics which it has not been possible to deal with adequately, of empirical data, constructional details and illustrations, experimental tables, etc., and the real scope increased correspondingly by deeper inquiry into the physical principles underlying the operation of the apparatus and equipment discussed. One of the primary aims in teaching should be to stimulate critical analysis and flexibility of outlook, and the author's treatment of the subject is unlikely to assist materially in this direction. The task attempted is made difficult by the rapid growth of the subject, and in these circumstances it is questionable whether any really useful purpose can now be served by books of this 'comprehensive' type.

DRIED FOODS

AT a joint meeting of the newly formed Nutrition Society and of the Food Group of the Society of Chemical Industry, held in the Great Hall of the British Medical Association on July 25, a series of papers was devoted to giving an account of the results that have recently been achieved in improving the quality of dried foods. The meeting was private, several hundred members being present. In the morning the chair was taken by Sir Edward Appleton, secretary of the Department of Scientific and Industrial Research, and in the afternoon by Dr. H. E. Cox, chairman of the Food Group, deputizing for Dr. L. H. Lampitt of Messrs. J. Lyons and Co. Ltd., who was unfortunately prevented from being present.

In introducing the morning session, Sir Edward Appleton told the meeting how the Food Investigation Board of his Department, under the chairmanship of Sir Joseph Barcroft, had realized the tremendous importance which must attach to the utmost economy in transport of foodstuffs, particularly overseas transport, under war conditions, and had been concentrating for some time on dehydration. It has been estimated that in peace-time we imported every year as much as three million tons of water with our foodstuffs.

He thought that history would show that science had made tremendous contributions in the present War and that these contributions had been made largely by anticipating needs. It was quite possible that the work that had now been done on dried foods would be far from the least of these. It had been realized that the nutritional quality of dried foods was of critical importance and the Medical Research Council had collaborated on this aspect at the Dunn Nutritional Laboratory, Cambridge. The work had been organized by Mr. Eric Barnard, director of food investigation, and carried out chiefly at Cambridge under the scientific leadership of Dr. Franklin Kidd, of the Low Temperature Research Station.

In an introductory paper covering all commodities, Dr. Franklin Kidd pointed out that fundamentally no new discoveries had been made but that, nevertheless, by bringing together what was already known in other branches of the food industry and applying the results to dehydration, it could now be said, in general, that the nutritive quality and palatability of dried foods such as meat, fish, milk, eggs and vegetables would be equal to that of those preserved by the established processes of canning and refrigeration. The main principles which had in general to be observed were to destroy the enzymes by a short heat treatment before drying; to maintain a low water content in the dried product during storage and distribution, which can only be done by shielding it from contact with air; to exclude oxygen or retard oxidative changes by the use of antioxidants and avoidance of contamination with traces of metal; to avoid temperatures during drying above a certain limit which can easily be determined for any product, but nevertheless to dry as quickly as possible; to avoid temperatures during drying at which bacteria will flourish; and, lastly, to select the best material as regards flavour, appearance and nutritive value and to treat it with scrupulous cleanliness during the manufacturing operations. We could not hope for good dried foods if drying were used as a means of disposing of fresh food which had deteriorated too far for distribution in the fresh condition.

As an illustration of the economy in space and weight Dr. Kidd stated that the requirement for a full normal dietary consisting of flour, biscuits, cereals, potatoes, vegetables, pulses, meats, soups, fats, sugar, eggs, fish and milk, in the requisite proportions and including packaging, would reduce to a quarter of its weight and volume.

Dr. E. C. Bate-Smith, Miss E. M. Cruickshank and Dr. J. G. Sharp described fully the process for the drying of meat in the form of a mince which, for storage and distribution, is compressed into blocks and packed in air-tight cans. It had been found that the digestibility of this meat was unimpaired and that when the drying was carried out between the temperatures specified (60° to 80° C.) there was little or no loss of vitamin B_1 during drying, nor was there any loss of nicotinic acid or riboflavin. Vitamin B_1 is also retained during storage, but the retention of nicotinic acid and riboflavin has not yet been investigated. The fat content of the dried meat was 30–45 per cent on a dry weight basis.

As regards egg it had been found that little denaturation and coagulation of the protein occurred in spray-drying if the temperature of drying, as measured by the outlet air temperature, did not exceed 70°. No loss of vitamins A and D was observed during the drying. There was a loss of 30 per cent of the vitamin B_1.

What was particularly aimed at both with regard to meat and egg was the full retention of the characteristic flavour, odour, colour and appearance of the fresh food. Quality grading was therefore being carried out by a system of tasting panels which have proved unexpectedly simple in operation and capable of repeating judgments with consistency and accuracy. Surveys had also been carried out to ascertain the sensitivity of the average consumer to unit differences on panel scoring and, for immediate purposes, the level of what may be described as public acceptance has been ascertained. If dried meat and dried egg are protected from the access of air and the uptake of water, they can be stored for long periods without loss of quality.

Dr. G. A. Reay of the Torry Research Station described the roller-drying of minced fillets of raw cod, haddock and whiting in about a quarter of a minute to a water content of 8 per cent. A better product was produced by mincing pre-cooked fish and drying on trays between temperature limits which have been determined. With both fish and meat it is preferable to mince after cooking, that is, following the natural shrinkage which occurs after coagulation has taken place.

Dr. R. J. L. Allen, Dr. J. Barker and Dr. L. W. Mapson described in detail the process of drying cabbage, carrot and potato. Each of these vegetables must be given a heat treatment ('scalding') before being dried and, for the protection of the ascorbic acid from oxidation, the addition of a small quantity of sulphite to the scalding liquor is very beneficial. The reconstituted and cooked dried cabbage and potato should contain at least 35 per cent of the ascorbic acid of the raw vegetable, which is as much as, or more than, is retained when fresh vegestables are cooked. There is practically no loss of carotene during scalding, drying or reconstitution and cooking.

While storage of the dried product in air, but at low water content, is possible for reasonable periods with cabbage and potato, carrot should always be stored in an atmosphere free of oxygen owing to the destruction of carotene by the oxygen.

In winding up the sessions, Sir Joseph Barcroft spoke briefly of the possible effect of dehydrated foods on the trend of national life and policy. It was clear, he thought, that dehydration plant would have to be situated where the food was produced and that we must realize that, with the possible exceptions of vegetables and milk, the dried foods we obtained would, for the most part, be dried overseas. If dried foods had a future it would obviously have profound reactions on the organization of transport and distribution. It was well worth facing this problem now because it would be much more easily dealt with when industries largely wrecked could be reconstituted on new lines than when normal industries would have to be remodelled at considerable loss. In particular, he wanted British agriculture to take advantage of dehydration as a means of getting the maximum production in its natural season. If British agriculture seized its opportunity, he believed the producer of good food would benefit, although the producer of inferior products might rightly regard dehydration as something of a menace.

The quality of dried foods prepared by the methods now being employed was not only high but it was ascertainedly so by assay for palatability, vitamin content, etc., and hence could be guaranteed. This he considered most important from the point of view of efforts to raise the nutritional status of the population as a whole. It was already clear that the price of dried foods would not exceed that of fresh foods and might be less owing to economies in cost of distribution and saving of wastage.

While it was impossible in so large a meeting for discussion to go into any detail, several interesting points were raised. Mr. Nevill Wright and several other speakers stressed the need of urgency and asked for information as to what steps were being taken to push forward with production of dried meat and vegetables. The question was raised as to what were the most suitable types of plant for drying different foods and, in particular, stress was laid on the importance of the efficiency of drying in terms of fuel consumption.

In reply to these points Dr. Kidd and Dr. Bate-Smith stated that stress had intentionally been laid on the importance of the pre- and post-drying treatment of the products and of the temperature limits during drying rather than on the exact specifications of the plant to be used. It was felt, in general, that while some adaptations might be necessary, the drying of meat and vegetables would not necessarily call for completely new types of plant design. In terms of the value of the material the cost of drying was negligible.

Dr. Colgate wanted to know whether it was possible to dry eggs without losing their beating quality, which contributed much to the value of the egg in the baking trade. He had not found even the best spray-dried egg equal to frozen egg pulp. Dr. Bate-Smith said that even egg dried out in a vacuum in a frozen condition had lost its aerating power to about the same extent as the spray-dried egg powder. However, this loss of beating quality could easily be overcome by the simple device of beating at an elevated temperature, for example, 40°. Even really poor spray-dried egg powder would give good aeration if the temperature of beating was raised to 50° or 55°.

Squadron Leader Macrae described experiences in the Royal Air Force. From every point of view these new dried foods were what was wanted. The men liked them and trials had shown that they got more vitamin C from dried cabbage than from fresh. This was due to the fact that the cabbage was dried in such a way as to preserve vitamin C while at the same time destroying enzymes which caused the loss of vitamin C by oxidation during cooking. The foods were easy to prepare and transport and they offered variety.

Mr. Charley and other speakers stressed the importance of easily prepared foods as a factor in family life, while others directed attention to their advantage in communal and emergency feeding. Mr. McLellan wanted more information broadcast as to simple methods for home-drying as an additional means of saving garden and allotment produce for the winter.

During the midday break a buffet lunch was served, and cooked dried foods manufactured by the improved processes described were sampled. Those present thus had an opportunity of confirming the claims made as regards their palatability.

DIGESTIBILITY OF HIGH-EXTRACTION WHEATMEALS

By T. MORAN and J. PACE

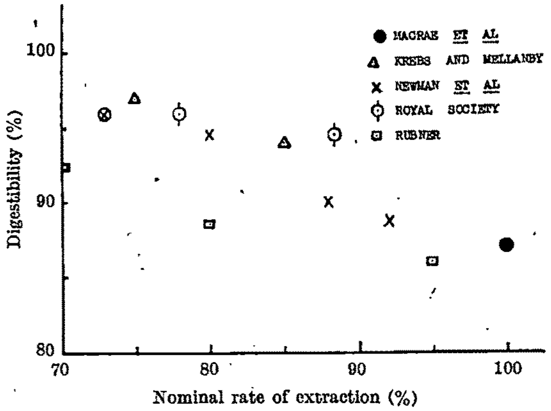
THE digestibility, in terms of energy, by human subjects of high-extraction meals (80–100 per cent extraction) is less than that of flour of 70 per cent or lower extraction. Recent work illustrating this is that of Macrae *et al.*[1], who compared 73 per cent flour with wholemeal (100 per cent), and Krebs and Mellanby[2], who compared 75 per cent flour with a sample of National wheatmeal (85 per cent). Unfortunately, there are no modern data on digestibility for meals between 85 per cent and 100 per cent. Older data exist[3], and it is usually the practice to make the rate of extraction the basis for the comparison of the results of different investigators. In the accompanying figure, these data are plotted in this manner and the wide variation in the results is immediately apparent. In this article we wish to emphasize that in digestibility experiments or calculations on wheatmeals the practice of making the rate of extraction the basis of comparison is fundamentally unsound and may give rise to misleading results and deductions even though the experimental technique of the test meals, etc., is completely satisfactory. At a given extraction the digestibility must depend also on the composition of the wheat grist, the conditioning of the wheat and the method of milling.

The wheat grain consists of endosperm, germ, seed coat (testa, hyaline and aleurone layers) and the shell or pericarp. The layers of the seed coat and pericarp together, with a varying amount of endosperm, constitute the bran; without the endosperm they can be regarded as 'pure bran'.

There seems little doubt, especially in view of the work of Macrae *et al.*[1] on wholemeal, that decrease in digestibility in passing from white flour to high-extraction meals is due to the presence of bran or bran layers rich in indigestible fibrous material. The pericarp or beeswing* includes the layers which contain the most fibre—two determinations gave figures of 21 and 23 per cent against 14 per cent for pure bran (see below)—and it is the presence of this fraction, either alone or in bran, which is mainly responsible for the lower digestibility of high-extraction meals. Our experience with National wheatmeal shows that the bulk of the contained bran particles are substantially full bran including the aleurone layer.

---

* Beeswing is a general term used by millers and may comprise the whole or part of the pericarp. The actual composition depends on the condition of the wheat and the point of separation in the mill flow; examination of one particular sample from the purifiers showed that it contained all four layers of the pericarp although the amounts of the two inner layers seemed to be slightly less in proportion.



Fibre content is a sensitive index of the amount of indigestible materials in the bran or its separate layers. The size of bran particle has little or no effect[1]. The white flour basis itself has a small fibre content which is difficult to determine accurately but is in the range 0–0·2 per cent; much of this fibre will be from the cell walls in the endosperm. As we move beyond 73 per cent extraction the increase in fibre content is due mainly to bran or its components.

On the basis that the fall in digestibility is proportional to the fibre content it is possible to calculate theoretical digestibility figures for wheatmeals of different fibre contents. The wholemeal used by Macrae *et al.* had a fibre content (reckoned on a 15 per cent moisture basis) of 1·80 per cent and a digestibility of 87 per cent. The 73 per cent white flour used had a fibre of 0·15 per cent and a digestibility of 96 per cent. On the assumption given above it follows that each increase of 0·2 in fibre content (above 0·15) leads to a decrease in digestibility of about 1·1 per cent. Figures calculated on this basis are shown in Table 1.

TABLE 1.

Fibre content	0·35	0·55	0·75	0·95	1·15	1·35	1·55	1·75	1·95	2·15
Digestibility%	95	93·9	92·8	91·7	90·6	89·5	88·5	87·4	86·3	85·2

The only experimental figure available for checking this is that of Krebs and Mellanby[2], who found a digestibility of 94 per cent for an 85 per cent extraction meal which had a fibre content of 0·45. From Table 1 a meal with this fibre content has a calculated digestibility of 94·4.

It is also possible, taking average figures for the composition of the wheat grain—endosperm and germ 86–87 per cent; pure bran 13–14 per cent—to calculate a figure for the digestibility of pure bran. The figure obtained depends on the value taken for the digestibility of pure endosperm. It is most probable that this is in the limits 97–99 per cent. Taking these limiting figures, the digestibility of pure bran works out at 23 per cent and 11 per cent respectively. The fact that the digestibility of the crude fibre alone in wheatmeal bread is of the same order[1] suggests that the particles of bran pass through the gut substantially unchanged except that the attached endosperm and possibly the aleurone layer are digested. At the same time the vitamin B_1 contained in the bran (including that in the pericarp and testa) must presumably be available since, *in vitro*, it is extracted by dilute acid.

Commercially, bran consists of pure bran plus endosperm, and the digestibility of any commercial sample will depend on the endosperm content.

It is of interest to illustrate the points discussed above by two examples.

Example 1

Typical relative proportions of the various milling fractions and the fibre contents of these fractions have been published[4] (cf. also Table 2). From these data we can compound wheatmeals corresponding to different nominal rates of extraction as follows:

% *Extraction*
$80\% = 73(a) + 5(e) + 2(d)$
$85\% = 73(a) + 5(e) + 2(d) + 5(c)$
$90\% = 73(a) + 5(e) + 2(d) + 6(c) + 4(b)$
$95\% = 73(a) + 5(e) + 2(d) + 6(c) + 9(b)$
$99\% = 73(a) + 5(e) + 2(d) + 6(c) + 13(b)$

We can calculate the corresponding fibre contents and hence the calculated digestibilities. These data are brought together in Table 2.

TABLE 2.

Milling fraction	% of whole wheat	Fibre %	Rate of extraction %	Calculated Fibre %	Calculated Digestibility
Wheat	100	1·8			
(*a*) Flour	73	0·2	80	0·55	93·9
(*b*) Bran	13	8·0	85	0·90	92·0
(*c*) Fine bran	6	7·0	90	1·30	89·7
(*d*) Purifier tails	2	6·1	95	1·65	87·8
(*e*) Reduction roll tails and mill finish	5	3·6	99	1·80	87·0

Example 2.

Mr. A. G. Simpson has prepared a series of straight-milled high-extraction flours on the experimental milling plant at St. Albans. The grist contained 70 per cent No. 1 Manitoba and 30 per cent English and was milled at approximately 14 per cent moisture giving flours of approximately 13·5 per cent moisture content. The fibre contents of the wheat mixture and the flours were determined and these are shown together with the calculated digestibilities in Table 3.

TABLE 3

Flour or meal (% extraction on a clean wheat basis)	%Fibre (on a 15% moisture basis)	Parts of pure bran	%Digestibility (calculated)
75	Trace	—	97·0+
85	0·55	3·9	93·9
90	1·0	7·1	91·5
95	1·5	10·7	88·7
100	1·95	13·9	86·3

Samples of bran from three varieties of wheat all freed from endosperm by treatment with dilute lactic acid gave fibre contents ranging from 12·9 to 14·2 per cent (on a 15 per cent moisture basis). Similarly, for a wheat mixture of fibre 1·95 per cent (as in Table 3) and assuming it contains 13–14 per cent of pure (clean) bran, calculation gives the fibre content of the pure bran as 14·4 per cent. On the basis of an average fibre of 14 per cent, column 3 in Table 3 gives the equivalent parts of 'pure' bran in each meal.

An average composition of commercial bran (pure bran and endosperm) from wheat conditioned for the milling of white flour is given below together with an analysis calculated for pure bran. This can only be a proximate analysis because the endosperm attached to commercial bran is richer in oil, protein and ash than the bulk of the endosperm. Incidentally, it would appear that the amount of endosperm attached to the commercial bran was approximately 40 per cent; with the drier milling of National wheatmeal the amount of attached endosperm will be much less and figures for the fibre content of the bran may now reach 11·5 per cent, indicating about 18 per cent of endosperm.

TABLE 4

	Commercial bran%	Pure bran%
Moisture	12·5	12·5
Oil	4·7	8·3
N × 5·7	15·0	16·8
Ash	4·7	8·3
Fibre	7·9	14·0
Non-N material	55·2	40·0

Comparison of Tables 2 and 3 illustrates clearly the fact that meals of nominally the same extraction may have quite different fibre contents and hence different digestibilities. The same fact has emerged even more clearly in a survey of National wheatmeal[5].

Apart from the method of milling, the actual fibre content of the wheat mixture used must also be a factor. For individual wheats this may vary[4] from 1·7 to 2·9, with an average for a present-day grist of about 2 per cent.

With increasing extraction the digestibility of each extraction increment will depend upon the corresponding increase in fibre content. As a matter of interest, for the meals in Table 3 the digestibilities of the fractions 85–90 per cent, 90–95 per cent and 95–100 per cent are 50, 40 and 40 per cent respectively.

All the experimental fibre values quoted in this paper were determined by Mr. R. H. Carter by a modification of the official method which he has developed for wheatmeals; each value can be reproduced to within 0·05. We are also indebted to Squadron Leader T. F. Macrae for allowing us to see the typescript of the paper by him and his collaborators now in the press of the *Journal of Hygiene*, and to Dr. C. R. Jones for much helpful criticism.

RADIATION FROM THE SUN

By DR. C. E. P. BROOKS

ALL weather, and all life, on the earth are derived ultimately from the sun, and knowledge of the radiation emitted from the sun may be regarded as one of the fundamental sciences. Most of our knowledge of this important subject has resulted from the work and enthusiasm of one man, Dr. C. G. Abbot, of the Astrophysical Observatory of the Smithsonian Institution, who has carried on the work for a generation in the face of many difficulties and much discouragement. The problem is indeed a difficult one, for between the sun and the earth is interposed the atmosphere, and the radiation which reaches the surface is weakened by absorption and scattering. Water vapour, dust, and to a less extent ozone are the worst enemies, and a large part of vol. 6 of the Annals of the Astrophysical Observatory is occupied in describing the continuous attempts to overcome them during the years 1931–1940*. What might have been an even less surmountable enemy, the financial one, has been vanquished mainly with the help of Mr. John A. Roebling.

The difficulties of observation are lessened by making observations at as high a level as possible, to diminish the thickness of the atmosphere traversed by the sun's rays, and in a dry climate to minimize the loss of observations by cloud and also the weakening of the radiation by water vapour. Further, since in spite of all precautions the effect of varying weather conditions cannot be entirely eliminated, several stations must be used distributed as widely as possible in both hemispheres. For the purposes of supply the stations must also be reasonably accessible. Dr. Abbot has sent out many expeditions to test promising localities, but in the present volume the observations from only three are utilized: Montezuma, at a height of 8,895 ft. in Chile, which is the best station; Table Mountain, California (7,500 ft.) and Mount St. Katherine, Egypt (8,500 ft.). Observations were also made for a number of years at Mount Harqua Hala in Arizona, but have not yet been worked up owing to instrumental difficulties, and at Mount Brukkaros in south-west Africa, which though almost cloudless, proved to be too dusty.

The object of the observations is to determine not only the average amount of solar radiation received at the limits of the earth's atmosphere, the so-called 'solar constant', but also its variations from day to day. Since these amount to little more than 1 per cent on either side of the mean (which is still set at 1·94 cal./cm.²/min.) great precision is required both in observation and reduction. Precision in observation is obtained by the refinement of instruments. Direct measurements are made with Abbot's silver-disk pyrheliometer which serves as a permanent standard, and a modified form of Ångström's electrical pyrheliometer to give accuracy and speed in the daily observations. The loss by scattering is given by the pyranometer, which measures the brightness of the sky near the sun and hence the haziness of the air. These instruments give the total radiation falling on them, but since the radiation of different wave-lengths is differently weakened in its passage through the atmosphere, it is also necessary to obtain, with the bolometer, records of the whole

*Annals of the Astrophysical Observatory of the Smithsonian Institution. Vol. 6. By C. G. Abbot, L. B. Aldwich and W. H. Hoover. (Publication No. 3650.) Pp. viii+207+7 plates. (Washington, D.C.: Smithsonian Institution, 1942.)

spectrum from infra-red to ultra-violet. These nstruments are described and illustrated in Chapter X, which then goes on to a detailed account of the technique of reduction. The principle is very simple; the higher the sun the less the thickness of the atmosphere traversed and the greater the radiation. Hence, if the state of the atmosphere remains unchanged, a series of observations at different hours, preferably in the morning, can be extrapolated to give the radiation at zero air-mass, that is, the 'solar constant'. In the full or 'long' method computations have to be carried out for about forty different waveengths, and even with the help of a special slide-rule they are laborious, but Dr. Abbot has been able to devise short cuts without appreciable loss of accuracy. The derivation of the 'short' method is described in detail but cannot be summarized here.

Dr. Abbot and his colleagues are continually improving their methods, and in order to maintain a homogeneous series of data, it was necessary to re-compute some of the earlier observations. This has now been done, and no less than seventy-eight pages of the report are occupied with the determinations for nearly every day from August 29, 1923, to September 29, 1939. The result is a series of "preferred" values of the solar constant, but even these are not always quite final. Some of the values show improbably large jumps from day to day, and these were checked by examination of the variations of the short-wave spectrum alone. If these gave more reasonable variations, the "preferred" values were adjusted accordingly, as a series of "improved preferred" values. Some of the resulting changes are relatively large, as much as 1 per cent, and this must to some extent impair confidence in the accuracy of the individual daily values. Dr. Abbot indeed admits as much. From a comparison of the results at three stations, he estimates the probable accidental error of a single daily value as only 0·16 per cent, but he expresses the view that only means of ten days or longer can be regarded as really reliable. Ten-day and monthly means are given from August 1920 to September 1939.

The last part of the volume is concerned with the periodogram analysis of these data. The method used is not described in detail but was apparently graphical; short periodicities were "disclosed" by inspection and removed, disclosing longer periodicities and so on. The method is dangerous, giving rather free play to preconceived ideas of the lengths to be expected, and since all those found are integral parts of 273 months, a check by rigid Fourier analysis would have been both simple and desirable. Dr. Abbot's objection to this is that none of the periodicities is of sine form. He gives an illustration of the determination of three periodicities, and remarks, "We think readers may not be too favourably impressed by the comparison of the 34-month periodicity". He is quite correct in the case of one reader at least; practically the whole of the amplitude found results from the enormous range of the first of the six waves shown. His justification is that the reconstructed curve agrees closely with the original; this claim would be legitimate if all the fourteen waves were of sine form, but is doubtfully so with the complicated forms shown, each of which could be expressed as the result of several sub-waves. The lengths determined range from 8·3 to 273 months; recurrences at intervals of twenty-seven days associated with the sun's mean rotation period are also illustrated and there is a tantalizing reference to the temporary existence of shorter periods measured in days. No relation is found between solar radiation and sunspot numbers.

The great future importance of the study of variations in the solar constant lies in its probable application to weather forecasting. Periodicity is the most obvious method of this application, for if the solar variations are truly periodic they should be reflected, in favourable circumstances, in periodicity of weather. From the point of view of the Astrophysical Observatory, however, this is only a by-product. Dr. Abbot casually mentions that he verified the lengths of the solar periodicities of 8–68 months in meteorological data for a hundred years for three stations (with due allowance for seasonal changes) and he claims two-thirds success for long-period rainfall forecasts, but until the relations between solar and terrestrial phenomena are more fully understood forecasts are probably premature. His great service still lies in the record itself rather than in its applications.

OBITUARIES

Prof. W. H. Young, F.R.S.

William Henry Young, who died in Lausanne on July 7 when nearly eighty, was one of the mathematicians who had contributed most to the revival of English mathematics during the last fifty years.

Young was born in London on October 20, 1863; his family had worked in the City for some generations. His first education was at the City of London School: the headmaster, Abbott, had been a schoolfellow of his father. He went up to Cambridge, at Peterhouse, in 1881, was fourth Wrangler in 1884, and a fellow of his College from 1886 until 1892; in 1939 he was made an honorary fellow. In his early graduate years he did a great deal of teaching, both as a private coach (as was usual with Cambridge mathematicians then) and more officially as a lecturer at Girton. In 1896 he married Grace Chisholm, who had been one of his pupils and was also a fine mathematician. He was the first Hardinge professor of mathematics in Calcutta from 1913 until 1916, professor of the philosophy and history of mathematics in Liverpool from 1913 until 1919, and professor of pure mathematics in Aberystwyth from 1919 until 1923; but the first two of these chairs were rather 'occasional' appointments, and it is something of a scandal that he should never have occupied a regular position really worthy of a mathematician of his rank.

Young became a fellow of the Royal Society in 1907, and was Sylvester Medallist in 1928; was de Morgan Medallist of the London Mathematical Society in 1917, and president from 1922 until 1924; and president of that rather unhappy body, the International Union of Mathematicians, from 1929 until 1936. He leaves his wife and five children, two of whom are also well-known mathematicians.

Young wrote three books (two in collaboration with his wife) and about two hundred papers, all crowded into a little more than twenty years of his life; he was over forty when his first important papers were published. He belonged to the generation of mathematicians which includes Burnside, A. C. Dixon, Forsyth, Hobson, Love, and MacMahon, and was fully the equal of any of them in originality and power; but all of them had established their reputations before he began, and this late start was a serious impediment in the way of his recognition. This was also delayed by a certain conservative hostility to the subjects which he represented, and which scarcely anyone in England understood.

'Complex' function-theory had been introduced to Cambridge a little before (in a rather ill-digested form) by Forsyth, but the 'real' theory was still practically unknown. Hobson and Young were the first true English 'analysts', and "The Theory of Sets of Points", published by the Youngs in 1906, the first real English book on analysis. This is a first-rate book both in substance and in presentation, and it is most regrettable that it should never have been rewritten, in the light of later advances, and reprinted. But all Young's books were comparatively unsuccessful in England. His Cambridge Tract, "The Fundamental Theorems of the Differential Calculus" (1910), though much of its content is now 'classical' and is reproduced in the standard French courses of analysis, never went into a second edition; and the joint "First Book of Geometry", a most interesting and original 'book for children', written in 1905, was 'a complete flop' at home, though it has been translated into four foreign languages.

The theory of functions of a real variable has been completely rewritten since 1900. The remaking began with Borel's famous monograph "Leçons sur la théorie des fonctions", published in 1898. Among those who have remade it Lebesgue, by general consent, stands first; but there is no one else who has contributed more than Young. Young's first work was independent of Lebesgue; he had found definitions of measure and integration different in form from, and in some ways more natural than, Lebesgue's, but equivalent in essentials. He was anticipated by some two years, and the disappointment was a blow; but he recognized the anticipation magnanimously—"the Lebesgue integral" is his own phrase—and set himself whole-heartedly to work at the fuller development of the theory: he was the first, for example, to find a really satisfactory synthesis of the work of Stieltjes and Lebesgue. But his interests were not at all confined to the theory of integration; there is scarcely a chapter of real function-theory on which he has not left his mark. Thus he rewrote a large chapter of the differential calculus, and the theory of Fourier series, and other orthogonal developments, are full of striking theorems discovered by Young.

G. H. HARDY.

Sir Alfred William Flux, C.B.

ALFRED WILLIAM FLUX, who died recently in Denmark, aged seventy-five, was successively mathematician, economist and statistician. Successively, because after being classed as one of the Jubilee Senior Wranglers in 1887, he came under the influence of Alfred Marshall (who had succeeded to the chair of political economy at Cambridge in 1885), was one of the foundation members of the Economic Society (1890), and from 1893 until 1908 was a teacher of economics, first at Manchester and then at McGill University, Montreal.

Flux's main interest was not in the development of the mathematical theory of economics, but in its practical applications to commerce from the statistical point of view. He had been elected a fellow of the Statistical Society in 1893. Though he joined the Econometric Society in 1934, he appears never to have used mathematics in his writings, except in his "Economic Principles" (1904), where, following Marshall, he gave them a subsidiary position. Indeed, he publicly deprecated mathematical tools except as a personal background to verbal analysis. In 1908 he returned to England and was attached to the Board of Trade until his retirement in 1932. During this period he was a very active participant in the work of the Royal Statistical Society, as member of council from 1908, honorary foreign secretary from 1925, and president during 1928–30. Soon after 1932 he made his home in Denmark, Lady Flux's native country, and during part of each year worked at the League of Nations in Geneva. The outbreak of war found him in Denmark.

Flux is best known because of his work on the British Censuses of Production. The first Census (1907) was already organized when he joined the Board of Trade, but he became director in 1911 and wrote the Final Report. He was responsible for the Censuses of 1911 and 1924 and for the initiation of that of 1930. Apart from the normal reports on production, he made three important developments. First he built up estimates of the total national income from the side of production, and contrasted and compared the results with earlier estimates based on the aggregate of individual incomes (Giffen's method); this analysis is of far-reaching importance (*J. Roy. Stat. Soc.*, 1913 and 1929). Secondly, he initiated an index of production, for which the Census provided the weights attached to the different quantity series (*J. Roy. Stat. Soc.*, 1927). Thirdly, he reconstituted Giffen's index of wholesale prices, again using the Census for weighting (*J. Roy. Stat. Soc.*, 1921). These results are now well known as the Board of Trade's Index-numbers of Production and of Wholesale Prices, though from time to time details have been modified.

The Board of Trade and its offshoot the Ministry of Labour have frequently been recruited from the ranks of trained economists who have brought wider views than are commonly taken by those without outside experience. This procedure has been abundantly justified by the importance and originality of the work which has here been too briefly summarized.

A. L. BOWLEY.

Dr. F. Dawtrey Drewitt

DR. FREDERIC GEORGE DAWTREY DREWITT, the biographer of Jenner and historian of the Chelsea Physic Garden, died at his home in Kensington after a long illness on July 29 at the age of ninety-four. He was educated at Winchester and Christ Church, Oxford, where he gained a second class in the School of Natural Science and received his medical training at St. George's Hospital. He qualified in 1876, and after being physician to the Victoria Hospital for Children during 1881–97 and at the West London Hospital during 1882–1902 he gave up medical practice for more congenial pursuits.

In 1903 Drewitt became a member of the British Ornithologists' Union, and afterwards served on the councils of the Zoological Society, the National Trust for Places of Interest or Beauty and the Society for the Promotion of Nature Reserves. He was best known, however, for his connexion with the Chelsea Physic Garden, on the board of management of which he had represented the Royal College of Physicians since 1921, and he was vice-chairman from 1929 until a few months before his death.

Drewitt's work entitled "The Romance of the Apothecaries Garden at Chelsea", which first appeared in 1922 and reached its third edition in 1928, contains a delightful account of the history of the Garden, including mention of the distinguished men connected with it, such as Sir Hans Sloane, Linnæus and Sir Joseph Banks, its most remarkable trees and other plants, and the present botanical research which is being carried out there. His further interest in botany is shown by a little book on the Latin names of common flowers, published in 1927. His "Life of Edward Jenner, Naturalist and Discoverer of Vaccination", of which the second edition was published in 1933, contains besides the description of the introduction of, and opposition to, vaccination, a lively account of Jenner's early life as a country practitioner and his observations on natural history. In 1931 Drewitt published for the first time "The Note-Book of Edward Jenner in the Possession of the Royal College of Physicians of London, with an Introduction on Jenner's Work as a Naturalist", in which he dealt with Jenner's friendship with John Hunter, Dean Buckland and Sir Humphry Davy. In addition to these works on natural history, Drewitt was the author of "Bombay in the Days of George IV: a Memoir of Chief Justice Sir Edward West", published in 1907.

There is no better example of the truth of Buffon's well-known aphorism than that given by Drewitt, whose polished and kindly nature was reflected in his style. His versatility was shown by his being an accomplished artist and twice exhibiting at the Royal Academy. He had many friends not only in the medical profession but also among laymen, the most notable of whom was Ruskin. He married in 1887 but left no issue.

J. D. ROLLESTON.

WE regret to announce the following deaths:

Dr. Arnold Berliner, founder and formerly editor of *Die Naturwissenschaften*.

Mr. D. B. Mair, formerly assistant Civil Service Commissioner and a distinguished mathematician, on July 21, aged seventy-four.

Sir Allen Mawer, F.B.A., provost of University College, London, an authority on English place-names, on July 22, aged sixty-three.

Prof. John H. Salter, formerly professor of botany in the University College of Wales, Aberystwyth, known also for his work in ornithology, on August 5, aged eighty-one.

Prof. A. L. Selby, emeritus professor of physics in University College, Cardiff, on July 22, aged eighty-one.

Prof. R. Willstätter, For. Mem. R.S., formerly professor of chemistry in the University of Munich, on August 3, aged sixty-nine.

Sir Francis Younghusband, K.C.S.I., K.C.I.E., distinguished for his explorations in south-eastern Asia, on July 31, aged seventy-nine.

NEWS and VIEWS

Astronomy on Postage Stamps

THE dedication of the Mexican National Astrophysical Observatory at Tonanzintla in February last has been marked by the issue by the Mexican Government of a series of six postage stamps devoted entirely to astronomical subjects. The 2c., 5c., 10c., 20c. and 40c. stamps depict respectively the dark nebula in Orion, the solar corona as seen at a total eclipse, the open spiral nebula in Canes Venatici, the edge-on spiral nebula NGC 4594, showing absorption in the central plane, and the ring nebula in Lyra. The 1 peso stamp, departing from the principle of showing spectacular objects such as these, is an experiment which must surely be unique in philately; it depicts the Hertzsprung-Russell diagram connecting stellar luminosity with spectral type, with the main sequence, the giants, the supergiants and the white dwarfs all duly labelled. The significance of this diagram will certainly escape all but those fairly well grounded in astronomy, but the ordinary user of the stamps of lower denominations cannot fail to be impressed by the grandeur of the objects shown.

Functions of Works Managers

IN his speech in the House of Commons on July 22 on the work of the Factory Department of the Ministry of Labour and National Service, Mr. Ernest Bevin paid a well-deserved tribute to works managers. The works manager, he asserted, deserves more recognition than he had yet received, and the country owes much to him in this War, as well as to the mines manager, for overcoming problems which no Government department, scientific worker or technician could have foreseen. There is a very close understanding between the Factory Department and the works managers, who have much in common, being trained, to a very large extent from the same personnel and thus understanding not only each others' problems but each others' approach to the problems. He drew a distinction, which he thinks industry will have to face in the future, between what he called the working directorates who understand the actual operations of the job and he put these working directorates in the same category as works managers. He also emphasized the value of the newly established Factory and Welfare Board as a safeguard against rigid bureaucratic methods. It gives industry and public service a proper place in this branch of administration, and Mr. Bevin thinks that a board of this character will remain a permanent feature to enable us to surmount the changes and difficulties which will arise in our industrial system in the vexed and difficult times ahead. Referring to the Department's policy in encouraging the establishment of personnel managers in the larger factories, he believes that too much is often imposed on the works manager in receiving deputations and like matters and being expected to run the works as well. Much specialization is essential in handling such problems, and the personnel manager as part of the executive is a great asset in large works. Referring to hours of work, Mr. Bevin said that production and mobilization of man-power have now reached a point when matters can be tightened up in respect of hours of work, and the trend of his speech indicated a welcome determination to deal firmly with the question of excessive hours, which are so important a factor in absenteeism and in low production.

Cork Substitutes

As a result of the War, imports of cork have almost, if not entirely, ceased in various parts of the world. Consequently, ingenuity has had to be exercised in providing substitutes. For obvious reasons stoppers for bottles were one of the earliest articles for which replacement was required. One of the countries effected was India, where the imports of cork from Europe very soon ceased, and the need for a substitute material for use as stoppers in different types of bottles, and as liners for bottle crowns and so forth, became keenly felt. The Forest Research Institute at Dehra Dun took up the matter, as explained in a Leaflet No. 6, Utilisation ("Note on Some Experiments on Cork Substitutes", by Dr. N. Narayanamurti, J. N. Pande and D. C. Roy (Research Institute, Dehra Dun, 1941). Experiments were conducted on the production of corks made of wood, composition corks made of disintegrated tree barks and pith corks for hypodermic tabloid tubes. So far, experiments have shown the following suitable substitutes. Bottle stoppers: stoppers of *Cryptomeria japonica* wood suitably slotted and softened by chemical treatment; crown cork liners: composite cork made from *Erythrina suberosa* bark and bagasse fibre have been found suitable; corks for tabloid tubes: paraffin-impregnated sola pith is suitable. The methods of manufacture of these substitutes are described.

Nature Reserves Investigation Committee

A Nature Reserves Investigation Committee has been established with the following membership: Sir Lawrence Chubb (chairman), Mr. G. Dent, Capt. C. Diver, Mr. J. C. F. Fryer, Mr. N. B. Kinnear, Prof. W. H. Pearsall, Dr. J. Ramsbottom, Prof. James Ritchie, Prof. E. J. Salisbury, Dr. G. F. Herbert Smith (honorary secretary), British Museum (Natural History), London, S.W.7.

The object of the Committee is to examine proposals for the establishment of nature reserves as part of any general scheme of national planning; and to obtain information from such bodies or persons as may be directly or indirectly concerned with the formation, organization, or administration of nature reserves or sanctuaries. In particular, the Committee will inquire into the types and approximate areas of reserves and sanctuaries which should be provided to ensure the preservation of communities or species; the species of plants and animals which are in danger unless special arrangements are made to secure their preservation and reproduction; the localities where such reserves and sanctuaries should be situated; the extent to which the public should have access to the various reserves; and the most appropriate methods for acquiring, financing and administering the reserves.

Scientific Film Conference

The first Scientific Film Conference in Great Britain met in the County Buildings, Ayr, during August 1 and 2. In Ayrshire there are four scientific film societies in operation, while an Army and an Air Force camp also arrange periodic shows of scientific films. The Conference was attended by forty-three delegates appointed by the film societies, universities and technical colleges, research institutes, technical departments of local government bodies and the Association of Scientific Workers. Dr. Norman Wright, director of the Hannah Dairy Research Institute, Mr. Arthur Elton and Dr. Blodwen Lloyd presided at the three sessions held on August 1. The delegates decided to form a National Federation of Scientific Film Societies, which would co-ordinate the activities of a Scottish and an English association of such societies. The great need for the increased production and showing of good scientific films was stressed by Mr. Elton (Ministry of Information) during a symposium on "The Scientific Film", to which Miss Mary Field (Gaumont British), Dr. A. Clow (University of Aberdeen), Mr. Stewart Paterson (Ardrossan S.F.S.) and Dr. B. Lloyd (Glasgow S.F.S.), among others, contributed papers. There was general approval of a resolution that both the winning of the War and the planning of post-war reconstruction require the application of the scientific method, and that a wider understanding of this method could most readily be achieved through the medium of the film.

Library of the Philippines

Colonel C. P. Romulo, formerly a publisher in Manila, now aide-de-camp to General MacArthur, has reported in the *New York Herald-Tribune* of July 17 that the Japanese have destroyed by fire the Library of the Philippines at Manila. According to Colonel Romulo, the aim of this vandalism is to obliterate all reference to the United States and Great Britain and anything savouring of Anglo-Saxon culture and democracy. With this aim in view, the occupying forces have formed a Text-book Board comprising seven Japanese and three Filipinos, which is expected to see that no reference to the above countries or culture shall be available in schools. Colonel Romulo was awarded the Pulitzer Prize for 1941 for his interpretative articles on Japanese aims. It will be remembered that university buildings in Manila escaped damage during the attack on Manila (Nature, July 4, p. 20), and it would appear that the destruction of the Library referred to above occurred after the Japanese occupation.

Bournville Village Trust

Under the title "Sixty Years of Planning: the Bournville Experiment", the trustees of the Bournville Village Trust have issued an admirable illustrated account of the development of Bournville from the building of the factory there by Richard and George Cadbury in 1879, when the first houses were also built to provide accommodation for those of the workmen who had to live near the factory (Bournville Village Trust, Birmingham 30). Bournville Village as we know it to-day dates from 1895, and the land and houses were transferred to an independent body, the Bournville Village Trust, when the success of the Bournville Estate seemed assured in 1900. The trust deed laid down the broad lines of future development, and this pamphlet shows the many sides of the work at Bournville in their true perspective. Housing schemes, the reconditioning of slum property and the planning of both municipal and private developments, as well as research into building and planning properties all find some mention in a book which is of real topical value apart from its historical aspect as a popular account of a great pioneer development. The illustrations of amenities, community activities, the planning of and provision for recreation, as well as for cultural needs, the treatment of transport and road problems and the preservation of the countryside show what is possible with vision and forethought, and should give a further stimulus to that growing movement to use to the full the opportunities which the tragedies of war itself now afford us of rectifying the mistakes and failures of the past and our failure to plan harmoniously either the industrial towns or the countryside of Great Britain.

Indian Farming

The journal *Indian Farming*, now in its third year of publication, is issued by the Imperial Council of Agricultural Research of India and is a praiseworthy attempt to bridge the gap between cultivator and scientific worker. It is a monthly with a pleasant appearance of format and is copiously illustrated. It includes articles on breeds of Indian livestock, livestock products and crops, and the erosion problem receives due recognition. Shorter articles and reviews from all parts of the country help to provide a reasonably full conspectus of Indian agricultural problems and of the manner in which technical effort is being directed to meet them. All original papers have a practical bias, as, for example, the recent paper entitled "More Light on the Red-spot Epidemic", by B. L. Chona and G. W. Padwick (**3**, 70–73; 1942). This gives details of the infection of sugar-cane by *Colletotrichum falcatum*, which has led to sudden and almost complete failure of the variety *Co* 213 over a wide area: a new strain of the fungus, not observed before the epidemic, is described. A note on animal quarantine in the Provinces and States discloses that the Central Provinces alone have anything like a comprehensive organization. As a good example of the educative article may be mentioned "Propagation of the Apple in Kumaun", by R. S. Singh. The solar treatment of loose smut of wheat—a method evolved at Lyallpur from Jensen's hot-water treatment—has been described by J. C. Luthra (**2**, 416; 1941); it is very effective and furnishes a striking instance of extreme simplicity in a control measure well adapted for farmers. A new heavy-yielding and strong-growing variety of sugar-cane (*Co* 421), described by Ch. Kh. Mohammad (**2**, 140; 1941), seems to be especially suited to the Punjab, and its seed is being multiplied as rapidly as possible. V. R. Rajagopalan (**2**, 136–39; 1942) has established calcium deficiency as the cause of an outbreak of non-bacterial abortion in equines. *Indian Farming* gives much attention to processing and marketing, including the canning and dairying industries, and the grading of eggs and oranges, and whenever possible simple devices adapted to Indian conditions are described in order that quality shall be improved.

Montesquieu and Medicine

The issue of the bilingual *Schweizerische Medizinische Wochenschrift* of May 2 contains an article in French by Dr. Camille Dreyfus of Mulhouse on this subject, in which he declares that the author of "L'Esprit des Lois" and the "Lettres Persanes" deserves a place in the history of medicine which has not yet been accorded to him. In 1718, the Academy of Bordeaux, of which Montesquieu had been elected a member two years previously, had chosen as the subject of a prize "The use of the renal or atrabiliary capsules", the modern equivalent of which would be "The physiology of the suprarenal capsules". Montesquieu made a report on the essays submitted, in which he showed that none of the competitors was worthy of the prize, which was, therefore, not awarded. His "Observations sur l'Histoire Naturelle", which he submitted to the Academy in 1721, contained microscopical studies of the pigmentations of insects, the parasitic life of the mistletoe, the abdominal circulation of the frog, the foramen ovule and ductus Botalli and experimental researches on the nutrition value of vegetables. In spite of his satires on medical practitioners in "L'Esprit des Lois" and the "Lettres Persanes", it would be wrong to suppose that he was prejudiced against the medical profession generally. In a letter to his friend the Abbé de Guasco, he expressed his admiration and affection for Van Swieten, the celebrated Dutch physician, whom Maria Theresa had invited to Vienna to reorganize medical education. Montesquieu was also a friend of the Chevalier Louis de Jancourt, who contributed articles on physiology and pathology to the "Encyclopédie". The high esteem in which Montesquieu himself was held by a leading medical man of the time is shown by the following appreciation of him by Antoine Portal, the celebrated professor of anatomy at the Collège de France and the Jardin du Roy: "If Montesquieu had devoted himself to the study of anatomy he would perhaps have advanced this science as much as he did moral science." In conclusion, Dr. Dreyfus relates that Montesquieu was the author of a thought which alone should win him immortality: "If I knew something useful to my country but injurious to Europe and the human race, I should regard it as a crime."

American Health in Early War Months

According to an editorial in the April issue of the *Statistical Bulletin*, the organ of the Metropolitan Life Insurance Company of New York, the United States have enjoyed a period of remarkably good health during the months they have been at war. An improvement in mortality-rate during the first three months of 1942 over that in 1941 was reported for almost all the important causes of death, and no less than nine diseases have shown death-rates lower than ever before. These diseases included not only typhoid fever, scarlet fever, diphtheria, whooping cough, syphilis and appendicitis, but also such important diseases as influenza, pneumonia and tuberculosis, in which the mortality has been low in recent years. The 1942 record for the most important diseases of middle and later life, namely, cancer, diabetes and cardiovascular renal diseases is favourable compared with that of 1941, the death-rate from diabetes being down 10 per cent and cancer and the cardiovascular renal diseases each 3 per cent. One of the few diseases to show a rise in 1942 as compared with 1941 are diseases of the puerperal state, of which the rate rose from 4·1 to 4·5 per 100,000, or approximately 10 per cent. It is probable that the increase was due to the rise in the birth-rate and in the number of women exposed to the risks of pregnancy and child-birth. Another group of conditions in which there has been an increase in the death-rate were external causes, with the exception of suicide, which had declined. Homicides and accidents, especially accidents due to motor-vehicles, were higher than in 1941. The war deaths reported to the Company in the first three months of 1942, amounting to 5 per 100,000, accounted for a part of the rise in the death-rate from external causes.

Concrete Simply Explained

This is the title of a booklet which has been published by the Society of Engineers (war-time address, 56 Church Street, Weybridge, Surrey) as reprinted from the *Transactions* of the Society. It was written primarily for the training of concrete operatives by Victor S. Wigmore, and presents the subject in a simple manner which should make it valuable to all grades of workers on the staff of contractors or engineers. The reader is asked to imagine that he is on a site where concreting is about to take place and he is then introduced in turn to each of the ingredients—cement, sand, coarse aggregate and water—and finally to different processes of concreting.

Each section has been treated very thoroughly and in considerable detail as, for example, in the section dealing with cement, where the reader is informed regarding the best method of storing the bags to keep them dry and to facilitate their progress to the mixers. The usual procedure of taking a sample for test, the tests applied, and the processes of setting, hardening and ripening are explained and some warnings given as to possible mistakes such as that of allowing aluminous cement and Portland cement to be mixed together. In a similarly thorough and practical manner the other ingredients and the work of concreting are described and explained. As, in the rebuilding of our towns after the War, concrete will play a very important part and there will be a demand for men who know how to make concrete of first-class quality, it is to be hoped that civil engineering contractors will distribute this booklet widely among their staffs and responsible workmen.

Variations of Geomagnetism

H. D. Harradon, Department of Terrestrial Magnetism, Carnegie Institution of Washington, has given a short account of this subject (*Sky and Telescope*, 1, 8; June, 1942), commencing with the discovery of the secular variation by Henry Gellibrand in 1634—a discovery of considerable importance, especially for mariners. Since no observations are available prior to this date, attempts have been made to extend our knowledge of the earth's magnetism to earlier times by the study of the magnetization of eruptive rocks, baked clays and ancient potteries. In quite recent years magnetic data have been obtained from successive lava flows of Mount Etna, the assumption being that the lava retained the direction of the earth's magnetic field at the time of its solidification, but unfortunately the results have proved rather indefinite. More promising lines of research are found in the study of layers of Pleistocene clays from an old glacial lake near New Haven, Conn., and also of sediment taken from the floor of the Atlantic. In the latter case, where several thousand years of deposition were represented, there is the suggestion of a possible variation in direction of magnetization amounting to more than 60°—the greatest range in secular variation ever recorded. No theory up to the present has explained the mystery of these secular variations; they are probably connected with changes in the interior of the earth, regarding which there is mere speculation. The transient variations, among which the solar and lunar diurnal and the annual variations are the chief, are discussed, and a number of useful diagrams and charts illustrate the connexion between magnetic storms, auroral displays, sunspots, etc.

Horticultural Work on the Amaryllidaceae

Vol. 8 of *Herbertia*, the year-book for 1941 of the American Amaryllis Society (Pp. 180. Hamilton P. Traub (editor), Orlando, Florida), includes several short papers of scientific interest. W. M. James and F. T. Addicott have studied the causes of sterility in interspecific crosses within the genus Nerine, and find a possible explanation in the presence of extra chromosomes in some parents. There appears to be no correlation between chromosome numbers and flowering period, though there is a sharply marked geographical difference between early flowering species and later blooming kinds. J. Marion Shull shows that early flowering species of Hemerocallis have made their flower initials by the previous autumn, whereas later flowering kinds have no floral initiation at that time. "Food Manufacture and Flowering in the Daffodil", by Dr. John Grainger, relates climate, photosynthesis and flower formation. It is found that floral initiation begins when carbohydrate content of the bulb is maximal. The daffodil appears to provide a very efficient photosynthetic mechanism, and its carbohydrate is completely mobile. Optimum conditions for photosynthesis are provided by a high daily average of sunshine and a relatively low average temperature between 40° and 50° F. Albert W. Close directs attention to the use of sphagnum moss for the germination of seeds of difficult species, and the method has the advantage of almost eliminating the damping-off disease. Numerous shorter papers give information on various Amaryllid clones, their combination in breeding, and practical culture. The Society's score-card method for the horticultural evaluation of daylilies has been extended to Florida by John V. Watkins, Hamilton P. Traub and Wyndham Hayward.

Periodic Comet Forbes, 1929 ii

Harvard College Observatory Card 626 announces that van Biesbroeck found this comet as a fifteenth magnitude object on a pair of plates exposed at the 24-in. reflector, Yerkes. Its position on 15 June ·34763d. was, R.A., 0h. 04m. 25·11s., Dec. – 4° 50′ 18·7″. The comet showed a short tail 1′ in length in position angle 270°. In the "Handbook of the British Astronomical Association", 1942, Mr. F. R. Cripps has given the elements of the orbit and also an ephemeris from which the object was easily found. Perihelion passage occurred only half a day earlier than was assumed.

Announcements

Sir Harold Scott, director of the Bureau of Hygiene and Tropical Medicine, is retiring on August 31. The Secretary of State for the Colonies has appointed Dr. C. Wilcocks, assistant director of the Bureau, to be acting director.

The medical faculty of the University of Basle has conferred an honorary doctorate on Prof. Eugen Pittard, rector of the University of Geneva, on the occasion of his seventy-fifth birthday, in recognition of his services to anthropology.

Dr. S. F. Dorey, chief engineer surveyor of Lloyd's Register of Shipping, will deliver the Parsons Memorial Lecture of the Institute of Marine Engineers on September 16. The lecture will be on "Reduction Gearing for Marine Steam Turbines", and will be delivered at the house of the Institution of Mechanical Engineers.

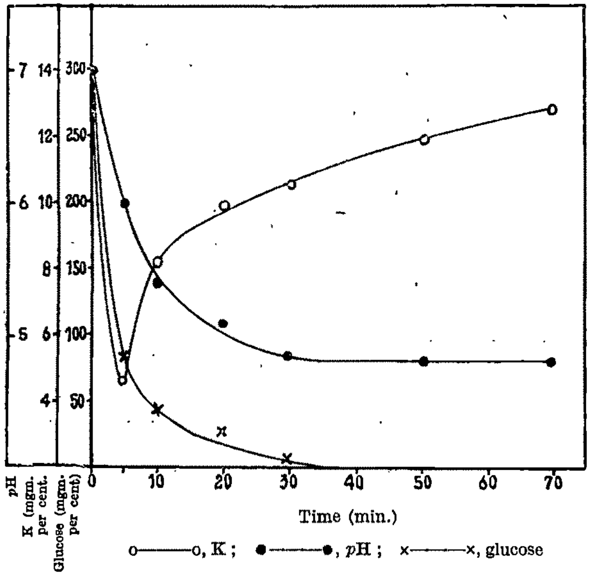
Potassium in Bacterial Fermentation

Verzar and Pulver[1] discovered that alcoholic fermentation by living yeast cells is accompanied by a striking shift of equilibrium between extracellular and intracellular potassium. The beginning of fermentation is marked by a vigorous intake of potassium from the surrounding medium. With the progress of fermentation the potassium is again liberated from the cells. No plausible explanation of this phenomenon has as yet been advanced.

It now appears that the 'potassium effect' is not confined to alcoholic fermentation by yeast but represents a general feature of glycolytic processes. We were able to demonstrate exactly the same phenomenon in the desmolysis of sugars (glucose, maltose) to lactic acid, hydrogen, etc., by *E. coli*. The accompanying table and diagram are representative of a series of experiments which yielded analogous results.



A suspension of *E. coli* in a solution of $M/60$ glucose, $M/250$ potassium chloride, $M/30$ (NaH_2PO_4-Na_2HPO_4), *p*H 7·05, was incubated at 41°; glucose and potassium were determined in samples drawn from the solution and cleared by centrifuging.

The intrinsic nature of the relationship between the 'potassium effect' and sugar metabolism in the bacteria is demonstrated by the following facts: (1) no such effect occurs when fermentable sugar is omitted from the phosphate-potassium chloride medium; (2) different experimental factors (temperature, *p*H, substrate concentration, aerobiosis or anaerobiosis) exert a parallel influence upon both fermentation-rate and potassium absorption.

Time (min.)	Glucose mgm./100 c.c.	Potassium mgm./100 c.c.	*p*H
0	300	13·9	7·05
5	79	4·7	6·00
10	43	8·2	5·40
20	32	9·9	5·10
30	9	10·4	4·81
50	0	10·9	4·80
70	0	12·9	4·80
90	0	13·5	4·80
120	0	13·8	4·77

The first period of fermentation is marked by a rapid and steep decrease of potassium in the medium. Then the process is reversed, the absorbed potassium being gradually released. The initial conditions are restored simultaneously with, or shortly after, the end of fermentation. At the turning point of the process, that is, at the maximum potassium intake and the beginning of potassium release, the fermentation substrate is still far from exhausted and acid production is still vigorously continuing. Therefore it is clear that the absorption of potassium is connected with some initial phase of the reaction chain of fermentation.

During the brief period in which potassium absorption occurs, glucose disappears from the medium at a rate far exceeding its 'fermentation-rate', as measured by acid formation. This discrepancy in the reaction balance could be accounted for by the detection of the formation in the cells of a non-reducing, hydrolysable polysaccharide which disappears in later stages of fermentation. *The conversion of sugar into a polysaccharide in the initial stage of sugar desmolysis has thus been established by us for bacterial fermentation*, as it has been for alcoholic fermentation in yeast and for glycolysis in muscle by Willstätter and Rohdewald[2,3]. There is a close coincidence in time between the maximum of polysaccharide accumulation and the maximum of potassium absorption in the bacteria. It seems reasonable, therefore, to ascribe to potassium a specific function in the synthetic reaction with which fermentation begins.

A detailed report on this investigation will be given elsewhere.

Thio-Ureas as Goitrogenic Substances

An attempt to isolate the goitrogenic substance present in rape seed[1,2] suggested the possibility of its being a derivative of this urea. Allyl thio-urea was therefore tested. Doses of 20 mgm. were given to rats daily by stomach tube for a period of eight weeks, after which the thyroids were examined. They had an average weight of 43 mgm., this being three to four times the normal weight. Histologically, the glands show extreme hypertrophy and hyperplasia, and almost complete loss of colloid. The administration of 50 mgm. daily by stomach tube, for ten days, produced identical histological changes in the thyroid, although the weight of the gland is not so great—average of 30 mgm. per 60 gm. body weight. This dose had no toxic effect. Preliminary experiments with 200 mgm. of thio-urea daily for ten days have produced similar results. The changes in both thyroid and pituitary are similar to those produced by feeding rats a diet containing rape seed[2,3].

Oxidation by Copper in Alcoholic Medium

NOT many examples of redox catalysis in non-aqueous solutions are known. The oxidation of ascorbic acid by copper in absolute ethyl alcohol is interesting because in many respects it resembles the corresponding oxidation in aqueous systems. In the experiments to be described, the absolute alcohol solution of ascorbic acid contained 1 mgm. of the acid per 2 ml. After the oxidation, the unchanged ascorbic acid was estimated by dichlorphenolindophenol titration of a 2 ml. sample diluted by addition of 10 ml. of 0·5 per cent aqueous acetic acid.

No data concerning the solubility of copper sulphate in absolute ethyl alcohol could be found in the available literature. This has been determined by weighing the anhydrous salt remaining after careful evaporation of a saturated alcoholic solution of copper sulphate. The solubility of $CuSO_4.5H_2O$ at 17° C. was found to be 0·0045 per cent, that of anhydrous $CuSO_4$, 0·009 per cent.

Salt dissolved	Conc. of $CuSO_4$	% Oxidation after 5 hr.	% Oxidation in the presence of $5 \cdot 7 \times 10^{-3}$ NaCl after 5 hr.
$CuSO_4.5H_2O$	$1 \cdot 9 \times 10^{-5}$ *M*	0	0
,, ,,	$9 \cdot 5 \times 10^{-5}$ *M*	63·6.	27·2
Anhydrous $CuSO_4$	$3 \cdot 8 \times 10^{-5}$ *M*	40·9	0
,, ,,	$1 \cdot 9 \times 10^{-4}$ *M*	100·0	45·4
Concentration of ascorbic acid $8 \cdot 5 \times 10^{-4}$ *M* in all cases.			

The catalytic action of copper sulphate is shown in the accompanying table. From this table also the inhibiting influence of sodium chloride can be seen. This influence is identical with the action of sodium chloride in aqueous systems.

Even greater than the activation of copper sulphate alone is that given by the pyridine-copper sulphate complex obtained by the action of pure pyridine on anhydrous copper sulphate and evaporation of the excess of pyridine. The crystalline salt so obtained was deep blue in colour and similar to salts obtained by Lang[1]. It contained $CuSO_4$ and pyridine in equimolar proportions. The solubility of this complex in absolute alcohol is 0·022 per cent, giving a greater amount of $CuSO_4$ in solution than did copper sulphate alone.

At a concentration of anhydrous copper sulphate of $8 \cdot 04 \times 10^{-5}$, 35·7 per cent of ascorbic acid was oxidized during six hours; at a concentration of copper sulphate – pyridine complex corresponding to a $CuSO_4$ concentration of $9 \cdot 06 \times 10^{-5}$, 100 per cent oxidation was found after 15 minutes.

Pyridine alone has also a catalytic effect, the concentration required to produce a given amount of oxidation being 1,000 times as great as that of copper sulphate.

It is noteworthy that these effects of pyridine and pyridine – copper sulphate complex in alcohol are quite different from those in aqueous systems, where pyridine alone (possibly by binding Cu) inhibits ascorbic acid oxidation, and the copper sulphate–pyridine complex is much less active than corresponding concentrations of copper sulphate alone.

Water present in alcoholic systems up to 1 per cent has no influence on the rate of oxidation. Higher percentages activate the oxidation, but this phenomenon is complicated by *p*H changes.

A full account of the work with the theoretical considerations will be published elsewhere.

Percentage of Water in Jelly-Fish

A LIVING specimen of *Aurelia aurita* about 4 in. in diameter was weighed by the displacement method[1] and the percentage of water found by distilling it under xylol[2]. The result was: water, 95·56 per cent; residue, 3·87 per cent; giving a difference of 0·57 per cent.

Since the distillation was carried out in what was practically a closed still, nothing should be lost. The difference, 0·57 per cent, represents (*a*) a trace of fat or other material dissolved by the xylol, and (*b*) a trace of water adhering to the rather large vessel which had to be used. The gonads would contain a trace of fat. The residue consists of salts, 3·2 per cent, leaving 0·67 per cent of dry protein; and since living material, such as muscle, in most marine animals, approximates to water 80 per cent and protein 15 per cent, we conclude that the 0·67 per cent of dry protein corresponds to about 4 per cent of protoplasm.

A number of distillations were carried out giving similar results, and it was intended to clinch the matter by carrying out a Kjeldahl estimation for nitrogen, but unfortunately no more living specimens arrived in the laboratory.

Some rather misleading statements have been made about Aurelia, and unfortunately these are finding their way into text-books. It has been stated that "The jelly-fish contains 99·8 per cent of water" and "The organic material in the body of medusæ amounts to less than 1 and most often to less than ½ per cent". Bateman[3] has criticized the first statement and shown it to be incorrect, but from theoretical grounds alone 99·8 per cent water is an impossible figure for Aurelia, for (*a*) an animal comprising 99·8 per cent water would float in the sea with a substantial portion of its body out of the water, which Aurelia does not do; (*b*) the density of Aurelia has been found, and it is obviously close to that of sea-water, which is 1·027 at 13° C. at Plymouth; if Aurelia were composed of 99·8 per cent water with a density of 0·99941, the density of the remaining 0·2 per cent would have to exceed that of mercury; (*c*) since Plymouth sea-water itself contains only 96·8 per cent of distilled water, surely this is the upper limit for any marine organism living in it.

We may conclude therefore that Aurelia comprises about 96 per cent water, 3 per cent salts, a trace of fat varying with the state of the gonads, and about 4 per cent of protoplasm.

Check-list of British Birds

MR. SETON GORDON, in his review of a "Check-List of British Birds" in NATURE of July 11, 1942, p. 40, remarks that, according to Cameron of Lochiel, the last year the osprey bred on Loch Arkaig was in 1908, and not 1902 as given by Mr. Witherby. There seems, however, to be some confusion regarding these dates. I was at Achnacarry for ten months from October 1902, and in the spring of that year the eggs were taken by a man from Fort William, who swam out to the island where the nest was situated. To guard against that happening again, the present Lochiel's father instructed his forester to put barbed wire round the lower part of the tree, and this I helped him to do.

These precautions were, unfortunately, unnecessary, as only one osprey returned in 1903, and I first saw it on April 15. It remained about the Loch throughout the summer, and several times I watched it fishing, also bringing sticks to the old nest which, by the end of the season, was about a foot higher.

For how many years the single bird returned to Loch Arkaig I have no personal knowledge, but I have been told that the last time it was seen was in 1910.

N. B. KINNEAR.

British Museum (Natural History),
South Kensington, S.W.7.

Regarding the above, Lochiel writes to me as follows:

"This shows the efficacy of the Secret Security Service set up by my father and continued by myself to keep the facts about the ospreys nesting absolutely *secret*. My father died in November 1905. We married in March 1906, and did not take up residence at Achnacarry until 1907, yet my wife remembers well seeing the ospreys and their nest on repeated occasions. As she was never at Achnacarry before we married and never saw an osprey in her life anywhere else, this surely is sufficient proof. Again, Norman MacRae (my piper and butler) also bears me out. He was never at Achnacarry before 1906 and his wife came to Achnacarry on October 31, 1907 (the ospreys always left before the end of September), yet they both remember the ospreys well, and going to see the nest. Mrs. MacRae, therefore, could not have seen them before the spring and summer of 1908. There is no possible doubt: the ospreys nested until the summer of 1908."

It is quite possible that, as Mr. Kinnear states, the osprey did not nest in 1903, but it is evident that they nested in the following years. Lochiel was living at Achnacarry and, as I know, always took a great interest in the birds, so it is inconceivable that both he and the witnesses he has quoted should be in error.

SETON GORDON.

Encouragement of Research in Industry

SIR LAWRENCE BRAGG says in NATURE of July 18, p. 75: "Lip service is paid to research because it is respectable and fashionable to do so, but responsible industrialists in private express their disappointment." That inventive talent is lacking seems doubtful. Even under conditions of complete detachment a continual flow of ideas cannot be maintained indefinitely; but when questions of plant, personnel, materials and time limit exist to cramp the style, a considerable proportion of the industrial scientist's fund of originality has to be transferred from the purely progressive to the task of adaptation to rapidly changing conditions. Provided the right men have been selected on the production side all is well; but if the research and development men are confronted with too much opposition to change, they will quickly become discouraged. It is, after all, their job to make improvements.

As to whether industrialists provide the right sort of conditions, it would probably be true to say that, on the whole, industrialists do not quite understand the research man, stand to some extent in awe of him, and thus fail in part to stimulate "the flow . . . of fundamental ideas which would profoundly affect our industries". The director of a few years ago who, showing a visitor round his works, stopped and asked of one of his research chemists: "Well, my man, and what have you discovered to-day ?", is not entirely extinct. But probably the root of the problem lies in the delegation of insufficient responsibility to research workers, even long after these have 'found their feet'. The suppression of executive ability in men of proved research capacity is surely to be deplored in many cases. Latent powers should be allowed for in men in harness, lest they remain too much in grooves.

It may help certain types of inventive genius to be assisted by a limited number of persons entirely devoid of original thought. These should be selected for their ability to interpret the wishes and record the ideas. To some extent they also act as a foil, but their importance is none the less on that account.

The industrialist who has not enjoyed a scientific training must find it hard to grasp the enormously dynamic nature of original research, or, when he sees frenzied activity over some apparently trivial matter, wonders whether sufficient eye is being kept on the main chance. Bearing in mind that 'spontaneous' research is bound to flow more readily than 'research to order', the time allowed for the latter should be on the liberal side. To some extent the research worker should be definitely encouraged to develop sidelines which spontaneously arise, as so much time would be wasted if at a later date he were asked to develop just that feature from scratch. It would be gratifying to think that research was sufficiently treasured in Great Britain to ensure facilities for developing what might be termed the 'overflow' of ideas of scientific workers engaged on specific products of research. Just as in chemical plants, 'waste' is frequently utilized to produce marketable by-products.

In many respects scientific workers themselves would get on faster if only they spent a small fraction of their time in striving each week for some improvement in their department. When actually engaged on research, they covet a lack of interruption. Then why not plan to be 'not available' at certain hours of each day ? An interrupted train of thought may mean ideas lost for good under present-day hectic conditions. It is, then, in the industrialist's interest to come to an understanding, so far as practicable, with his scientific personnel, on mutual intercourse. The use of a typist should by no means be restricted to purely clerical work. How many of Wordsworth's gems would have been lost to posterity were it not for sister Dorothea capturing the flowing words. If typists are not denied to directors and if poets find them useful, then surely the research scientist while manipulating should be encouraged to declaim his readings, his observations, his trains of thought to a shorthand typist seated within unobtrusive earshot.

Finally, it is possible that when engaged on pressing priority work, men will be tempted to work so fast that their readings are not properly recorded. This tendency to relapse into scrap-of-paper habits should be resisted firmly. One never knows when the story as a whole may not be wanted.

Science and Education

SCIENCE in relation to education has been prominent in NATURE for many months, but one aspect of the matter seems to me to deserve more attention: the social and historical setting of science. Sir Richard Gregory said[1]: "One reason why few men of science care to take an active part in politics, is that they do not feel able to effect [such] a transfer of their trained habits of thought" to the consideration of social and political problems. It certainly seems true that very few men of science can effect this transfer; nearly always judgment is heavily influenced by some bias, necessarily subjective. Moreover, this applies equally to men of letters, to men of business, to men in every walk of life. Therefore, we must think, not only of fitting the scientific man to play a conscious part in history, but also of giving the scientific outlook to the historian and the classic. When these men of the 'humanities' view social development with the same critical objectivity as the scientific man, they will be less likely to misguide us. The historian particularly needs the scientific attitude; for example, it is incredible that H. A. L. Fisher could write in 1936 ("History of Europe", p. 1207) on Hitlerite Germany: "Some items, such as the Second Punic War with England and the war of revenge on France, are no longer regarded as likely to be remunerative. Far more promising as a means of augmenting the territory of the Third Reich is the expedient of the plebiscite."

Now, I suggest that the inability of the man of science to carry his trained habits of thought into other fields, and the entire lack of the scientific attitude on the part of others, is due to the isolation of the several subjects in the schools during the formative years. The error of the schools is not that they give too much time to any one subject, but that they fail to integrate them all into a single whole. How can this be remedied? The progress of science is contained in the advance of history, and itself helps to shape that advance, affecting every branch of human culture. On this ground I make the following suggestions: (1) The approach to science should be historical, the fundamental principles being studied in their historical order, against a background of contemporary social development. Apart from the basic reason for this, any branch of science becomes more real, and so more interesting and educative, if studied in this way. (2) To effect the above there must be complete correlation between the science class, the history class, the literature class, etc., the several syllabuses being planned as parts of one whole, bringing out the mutual actions between the various forms of social activity, in such a way that the student applies the scientific method of thought to all his studies. (3) Modern ideas on science, not always more difficult to understand than the concepts of classical science, should be included, impressing on the student that no theory, however well established it may seem, can be final. (4) Science must be understood to extend beyond the confines of physics, chemistry and biology, to embrace all social phenomena, involving the introduction of elementary instruction on statistics. In the study of human behaviour, the student should acquire the same attitude of mind as in his study of physical or chemical phenomena; theory must be tested by experience, both in the continuum of social history and the laboratory.

There should be no difficulty in finding time for such a programme, if it be recognized that the achievement is not to be a vast store of factual knowledge, but an understanding of principles and methods, and appreciation of the part played by science in shaping human society, and the ability to find factual knowledge when it is required. Least of all should we move towards vocational teaching in the primary or secondary school.

[1] NATURE, March 7, 1942, p. 261.

Prof. A. R. Forsyth

MAY I correct Prof. Chapman on two minor points (NATURE, 150, 49; 1942)? Forsyth's Calcutta lectures, published in 1914, were on the theory of functions of two complex variables. His treatise on differential geometry, published in 1912, that is, before he went to Calcutta, is described in the preface as consisting of the substance of lectures delivered during his tenure of the Sadlerian professorship at Cambridge. In his retirement Forsyth produced, not two treatises, but three, the third, which appeared in two volumes in 1935 with the somewhat misleading title of "Intrinsic Geometry of Ideal Space", being an extension to n dimensions of the analysis which for three dimensions and for four had been developed in earlier works.

I would not impertinently praise Prof. Whittaker, but as I am writing I should like to express the indebtedness of all for his masterly discussion of the decline of Forsyth's reputation. We all know that fifty years ago Forsyth's name stood internationally for English pure mathematics; we needed to be told that it stood worthily.

RESEARCH ITEMS

Rice Field Insects

AN interesting Circular, No. 632, under this title by W. A. Douglas and J. W. Ingram, has been issued by the United States Department of Agriculture (Washington, D.C., 1942) which should prove of interest outside the United States. "Insect enemies of the rice crop differ", say the authors, "somewhat from those of other field crops and the methods of controlling them are different, because the rice fields are kept flooded with water during most of the growing period." Insect damage to growing rice is caused mainly by four species: the rice stinkbug (*Solubea pugnax*), two species of lepidopterous stalk borers (*Diatrœa saccharalis* and *Chilo plejadellus*) and the sugar-cane beetle (*Euetheola rugiceps*). There are other insects capable of inflicting some damage if the conditions of their environment become eminently favourable, but these four are of chief importance. The stinkbug sucks the contents from the developing rice grain, causing a total loss of all grains so attacked in an early stage of their development. The stalk-borers feed within the rice stalk, resulting in the loss by death of the developing rice panicle. The adult sugar-cane beetle gnaws young rice plants prior to the flooding in the spring, and newly emerged adults attack the nearby mature stalks when the field is drained prior to harvest; the stalks fall over and are thus prevented from being picked up by the harvesting machinery. All the important insects attacking rice in the field are alluded to but the above four are fully described and methods for their control are given. This circular makes its appearance at an opportune moment—since the rice crops of the United States and India must be of the first importance to the Allied Nations.

Hatching of Eggs

PARTRIDGES and grouse usually hatch 100 per cent of their eggs whereas domestic fowls frequently only hatch 75–90 per cent. R. K. Cole has discovered one reason for a reduced proportion of hatched eggs (*J. Hered.*, 33, 83–86; 1942). A lethal gene—talpid—was found in pedigrees of fowls showing infertility of a proportion of the eggs. Talpid causes the embryo to develop in an extremely abnormal manner. Most talpid embryos die about the eighth day of incubation, but a few may survive until the seventeenth day. The lethal gene is known to have been in the stocks of hens at Cornell for at least eight years.

Genetics of Natural Population

Linanthus Parryœ is a diminutive annual member of the Polemoniaceæ. It is found in the Mojave Desert of California, and has white or blue flowers. The numbers of the annuals vary considerably from year to year according to the amount of rain in the desert. In the locality studied by C. Epling and T. H. Dobzhansky (*Genetics*, 27, 317; 1942) the population can be considered an isolated one. Sampling of 427 stations, each half a mile apart, was made and involved 126,100 plants. A total of 113,955 white- and 12,145 blue-flowered plants were found, but the distribution of the two types was not uniform. Indeed only 108 blue plants were found outside three distinct and separate areas. A typical *U*-shaped curve of the frequencies of blue-flowered plants in the sub-populations indicates that small size of population is the chief contributory cause of the irregular proportion of blue- and white-flowered plants in the sub-divisions of the area.

A Cancerous Neoplasm of Plants

PHILIP R. WHITE described "A Cancerous Neoplasm of Plants Produced by Autonomous Bacteria-free Crown-Gall Tissue" in a paper read before the American Philosophical Society on April 24. Cancer is characteristically an independent and unrestrained, unphysiological, invasive, and malignant growth. Primary crown galls of plants possess to a marked degree the last four of these characteristics. They cannot, however, be considered independent, since they are caused by a bacterium, *Phytomonas tumefaciens*. Nevertheless, on certain hosts, especially among the Compositæ, there occur in many cases of crown-gall infection secondary tumours of unknown etiology arising at a considerable distance from the point of inoculation. Work carried out within the past two years has shown that tissues derived from these secondary tumours are bacteria-free by both bacteriological and serological tests. Tissues from the interior of secondary tumours have been isolated and grown *in vitro* for more than a year. In tissue culture they grow much more rapidly and in a much less organized manner than do tissue cultures taken from non-tumorous tissues. These tissue cultures can be grafted into either sunflower or artichoke plants, where they produce typical crown-gall tumours. Gall tissue can be transplanted from sunflower to artichoke and vice versa. In both hosts, as well as *in vitro*, they retain their characteristic independent, unrestrained and unphysiological manner of development. Their invasiveness is restricted by the rigid skeletal framework in which plant cells are regularly constrained to function, and their malignancy is likewise restricted by structural characteristics of plants. Nevertheless, it is believed that the cells of these tumours and of the tissue cultures derived from and giving rise to them, possess all the essential characteristics of cancer cells and therefore represent a new and potentially useful material on which to study the etiology of cancer.

Auriculas

THE neat growth and pleasing flower colour of garden auriculas result from some interesting structural mechanisms, which are discussed in a short paper by Sir Rowland Biffen (*J. Roy. Hort. Soc.*, 67, Pt. 6, June, 1942). Beautiful variations in flower colour are caused by the combinations of several factors—an imperial yellow colour, an anthocyanin (hirsutin), a buff yellow colour, and a white ground. Presence or absence of wax or 'meal' in the centre of the corolla also makes an additional contribution, while green, grey and white-edged forms are brought about by the plants' occasional demonstration of the foliar nature of the corolla lobes. Green-edged and grey-edged flowers occasionally occur on the same plant, and when this happens, the former spring from the base of the plant, while the terminal flower is grey-edged. A curious factor results from the presence of a 'paste' in the centre of some flowers, and there is evidence that this is a further indication of the leafy origin of the corolla. Chlorophyll may also occur in sections of the corolla other than at the edge. Zoned flowers thus arise, and another mutation gives striped flowers. The interactions of all these and other factors are discussed in the paper.

New Types of *Datura Stramonium*

Albert F. Blakeslee and A. G. Avery described "Nine Strikingly Diverse Types in *Datura Stramonium* with Location of their Determiners in a Single Chromosome" in a paper before the American Philosophical Society on April 24. The mutant characters discussed show wide departures from the normal type. One which has smooth, in distinction from spiny, fruits, has been classified as a distinct species, *Datura inermis*, although it differs from normals by only a single gene. This gene causes many changes beside the elimination of spines on fruits, such as shortening and thickening of petioles and internodes, increased inequality in paired branches, broadening of leaves, flattening of stigma and delayed fruiting. A type with short flowers and broad leaves is indistinguishable from another type which is determined by a different gene in another chromosome. A type which wilts in sunlight also mimics two other types brought about by different genes. One type induces early fruiting. A type has been called 'sickly' because its appearance resembles the effects of a virus disease or the environmental influence of lack of certain elements in the soil. One type usually branches with three, instead of two, forks but the environment affects the forking since plants which are genetically 3-forked occasionally have only two forks and normal plants may sometimes show three forks without being able to transmit the character to their offspring. One type brings about doubling of the chromosome number in eggs and pollen, one the production of lobed instead of round pollen grains and one causes the early death of the pollen grains affected without injuring the egg cells. By the breeding behaviour when extra chromosomes are present and by linkages between the characters in their inheritance, it has been shown that these nine types are determined by genes located in the 11·12 chromosome and at least eight of them in the ·12 half. It has been further possible by these methods to establish the approximate order and position of these genes within the chromosome.

The Lewiston-Auburn, Maine Earthquake of March 8, 1942

This earthquake has been investigated by William H. Weeks, *S.J.*, of the Observatory of Weston College, Massachusetts (*Earthquake Notes*, 14, No. 4; April 1942). The data used were the seismograms obtained at the observatory at Weston College, together with the returned questionnaire cards supplied by the United States Coast and Geodetic Survey, with which the epicentral region was canvassed. At Lewiston, near to which the greatest intensity was attained, small objects and vases were overturned and a few dishes broken. This indicates intensity IV on the Rossi-Forel scale. The sound which accompanied the earthquake was like "snow falling from a roof". The shock was registered on the seismograms at Weston at 23h. 38m. 32s. U.T. and appeared to come from an epicentre some 128 miles north-east by north of Weston. From all the data the epicentre appears to have been near latitude 44° 10′ N., longitude 70° 14′ W., which is about nine miles north-west of Lewiston, and the origin time 23h. 37m. 59s. U.T. Captain Heck notes that this district had not been entirely free from earthquakes during the last three hundred years, and that an earthquake disturbed approximately the same area on February 5, 1929.

Order in the Alloy Cu_3Au

Electron diffraction by the transmission method has been applied by L. H. Germer, F. E. Haworth and J. J. Lander (*Phys. Rev.*, 61, 614; 1942) to investigate superstructure as produced in the alloy Cu_3Au by various heat treatments. One of the purposes of the work was to extend the field of usefulness of electron diffraction by applying it to material which has been studied for many years by means of X-rays. The customary limitation of electron diffraction to the study of surface phenomena only is believed to be unjustified. Cu_3Au was chosen because it still presents unsolved problems in spite of many years study, because in the superlattice which is formed the copper and gold atoms can readily be distinguished by their widely different scattering powers and because the alloy is fairly resistant to corrosion. The changes up to 560° C. have been studied in detail. There seems to be no sudden change in the diffraction pattern corresponding to the alleged Curie point of order. The methods developed in the research are suggested as applicable to other alloys and to mixtures of metal salts.

Active Nitrogen

Two more papers in the series by Lord Rayleigh on active nitrogen have appeared (*Proc. Roy. Soc.*, A, 180, 123 and 140; 1942). From the experiments reported in the first paper, it is clear that the behaviour of the glass walls is very complex. Traces of oxygen or other impurities affect primarily the walls of the vessel and not the phenomena in the gas space. By a special device it is shown that when the behaviour of the gas is studied away from any surface, purest nitrogen is the best, and no favourable effect in promoting the active nitrogen phenomena is produced by adding a trace of oxygen. The second paper deals with the ionization associated with after-glowing nitrogen. It is found that this ionization is completely cut off if the testing vessel is separated from the after-glow by a silica wall. The ionization cannot therefore be directly produced by light within the range from λ 1850 to the visible. No increased current is observed when the surface action of the active gas is so vigorous as to make the testing cathode, of gold, red hot.

Stress Systems in Aeolotropic Plates

The stress distributors in an infinite plate containing a circular hole are greatly modified when the plate is no longer isotropic. A. E. Green continues the theoretical solution of such problems as may arise when a rivet is driven into a hole and pulled sideways (*Proc. Roy. Soc.*, A, 180, 173; 1942). The aeolotropic plate is assumed to have two mutually perpendicular directions of symmetry. Some examples of stress distributions are included which have non-zero force resultants on the edge of the hole, corresponding to cases in isotropic materials for which the solution is dependent on Poisson's ratio. The use of the complex variable makes the method of solution comparatively simple, and as an introduction to the work for an aeolotropic material the same method is applied to problems of stresses in an isotropic plate containing a circular hole in order to obtain results which Bicksley (*Phil. Trans.*, A, 227, 383) previously found by another method. Numerical work is carried out using the elastic constants found in experiments with specimens cut from the highly aeolotropic materials, spruce and oak.

EARTHQUAKES IN THE UNITED STATES DURING 1939*

A BOOKLET recently issued by the United States Coast and Geodetic Survey, entitled "United States Earthquakes, 1939", contains a very full account of the seismological activities of the department during 1939, together with a complete summary of the major results obtained. An important feature of the work is that it is fully co-operative with all interested in seismology, including the Weather Bureau, the Jesuit Seismological Association at St. Louis, universities, engineering companies, insurance companies and like commercial concerns, Science Service at Washington, the Seismological Society of America and interested individuals.

First come the non-instrumental results, chiefly obtained by the return of questionnaire cards by voluntary observers to local centres. This work is now fully systematized, and exceedingly useful results are obtained. In the booklet there is first a summary of the earthquakes according to the States concerned, the list including Alaska, Hawaiian Islands, Panama Canal Zone, the Philippine Islands and Puerto Rico. There follows a more detailed list classified by regions, dates, and the intensities of the shocks according to the modified Mercalli intensity scale of 1931. From this work it appears that the destructive and near destructive earthquakes of the United States during 1939 happened mostly in four large regions, which may be identified with (1) California, (2) the Appalachian Mountain region from near Chattanooga to near Boston, thence at right angles towards Montreal, (3) near the Mississippi–Ohio junction close to the rivers between St. Louis, Louisville and Memphis, and (4) the heights of the Rocky Mountains. Additionally, there were scattered epicentres throughout the country, probably the greatest being the one near Charleston.

Several universities and institutions send their seismograms and seismogram readings to the U.S. Coast and Geodetic Survey, and these are checked and printed along with the results obtained from the Survey's own teleseismic instruments. Altogether twenty-two observatories are involved in this way. From these readings along with those contributed by the Jesuit Seismological Association and others interested, epicentres throughout the world are calculated. In the publication under notice a complete list of such epicentres is printed for the years 1938 and 1939. Many of these have been mentioned previously in the columns of NATURE.

In order to furnish data suitable for the use of engineers, architects and others interested in the design of earthquake-resisting structures, the Survey instituted in 1932 a programme of strong-motion seismograph work. This makes use of seismographs placed in areas particularly susceptible to earthquakes, the seismographs being so designed that they only begin recording when the motion becomes sufficiently pronounced, and so that they are not unhinged by earthquakes such as are likely to occur (NATURE, Nov. 8, 1941, p. 551). The records obtained are interpreted on the assumption that the motion is simple harmonic, and the details published for each prominent pulse on each seismogram are: (1) earth wave period, (2) maximum acceleration, and (3) maximum displacement, together with remarks pertinent to the wave. During 1939, eight such earthquakes produced good strong-motion results. These were as follows: (1) Imperial Valley earthquake of March 21, which was recorded on the accelerograph at El Centro, some 24 miles N. 7° E. of the epicentre, the record showing a maximum acceleration on the horizontal component of about 26 cm./sec.^{2}. (2) Imperial Valley earthquake of March 24, showing details similar to (1) above. (3) San Diego County earthquake of May 1, recorded on the accelerograph at San Diego some 53 miles N. 23° E. of epicentre, with a maximum acceleration of about 3 cm./sec.^{2} on the north-south component. (4) Earthquake of May 4 near Boulder Dam recorded on the three accelerographs at Boulder Dam some four miles approximately N. 72° E. of the epicentre. The accelerograms here show the short-period motions characteristic of local earthquakes, the maximum acceleration being about 43 cm./sec.^{2} on the vertical component at the intake tower. (5) Western Nevada earthquake of May 11. This was recorded on the accelerograph at Hawthorne, Nevada, which is about 42 miles S. 85° W. of the epicentre, the maximum acceleration being about 8 cm./sec.^{2} on the horizontal components. (6) Northern Californian earthquake of June 22, with an epicentre off Cape Mendocino and recorded on the accelerograph at Ferndale. The maximum acceleration was about 15 cm./sec.^{2} on the south-west component. (7) San Diego County earthquake of June 24, which was recorded on the accelerograph at San Diego some 53 miles N. 23° E. of the epicentre. The motion on the accelerogram was somewhat irregular, the maximum acceleration being about 5 cm./sec.^{2} on the north-south component. (8) Southern California earthquake of December 27 with epicentre near Long Beach. This was recorded on the accelerographs at Long Beach, Vernon, Los Angeles Chamber of Commerce, Los Angeles Subway Terminal, and Hollywood, and on the displacement meter at Los Angeles Subway Terminal. At Long Beach, some three miles S. 75° W. of the epicentre, the maximum acceleration was about 14 cm./sec.^{2} on the east-west component. At Vernon, some fifteen miles N. 16° W. of the epicentre, the maximum acceleration was about 9 cm./sec.^{2}. At the Los Angeles Chamber of Commerce, some nineteen miles N. 22° W. of the epicentre, both the basement and the 11th floor accelerograms show irregular motion on the horizontal components, while the vertical components show a number of waves with 0·15 sec. period. At the Los Angeles Subway Terminal, about twenty miles N. 20° W. of the epicentre, the basement accelerogram and displacement meter records show small activity of an irregular character except on the vertical accelerogram. The 13th floor accelerogram shows considerably more motion, irregular on the south-west component, but comparatively regular on the others. At the Hollywood Storage Co., about 24 miles N. 29° W. of the epicentre, the seismograph on the adjoining lot and that in the basement of the storage building agree in showing slight motion of irregular character. The motion recorded in the penthouse is stronger and of comparatively long period, and is rather irregular except on the east-west component, which shows a maximum acceleration of about 3 cm./sec.^{2}. Several tracings of the accelerograph records are figured in the text. Maps with isoseismals are also given for the important earthquakes during the year.

During 1939, three tiltmeters were kept in operation on the grounds of the University of California at

---

* "United States Earthquakes, 1939", by Ralph R. Bodle. (Washington, D.C.: Government Printing Office.) 20 cents.

Berkeley with the active co-operation of the Seismological Station at that institution (Prof. Perry Byerly). Two required visible readings but a third automatically recorded pictures of the interferometer fringes every hour. No outstanding tilts could be associated with local earthquake activity. From October 1938 until January 1939 a triangulation resurvey was made of certain monuments in the locality between Petaluma and Point Reyes, California, originally established in 1928; about fifty stations were occupied. It is intended that periodic re-observations of this scheme will be made so that knowledge of possible earth movements may be obtained.

No tidal disturbances of seismic origin were noted on the gauges of the Bureau and co-operating stations during the year. One earthquake was reported felt by a vessel of the Coast and Geodetic Survey. This was on August 19 at Dutch Harbour, Alaska. Those aboard the ship felt four or five jolts.

ENTRY OF YOUTH INTO INDUSTRY

THE importance attached to the welfare of youth was reflected in the recent debate in the House of Commons on the Education Estimates; few of the many aspects of reconstruction problems after the War are more vital than that concerned with the welfare of youth. The memorandum on the problems of post-war entry of juveniles into employment, prepared by the London Regional Advisory Council for Juvenile Employment and recently submitted to the Ministry of Labour and National Service, emphasizes a vital aspect of juvenile welfare to which Political and Economic Planning directed attention in an admirable report, "The Entrance to Industry", so long ago as 1935. The memorandum adds little to what is contained in that report, but its arguments are ably reiterated. They are still valid, for while some progress has been made in regard to the provision of the social services required, we have scarcely begun to implement the long-term programme envisaged in the P E P report. Any charter of youth that may be promulgated will fail of its purpose if it does not receive the fullest consideration of all that is implied in the vital question of entry into employment. The plea of the London Regional Advisory Council that the economic aspect of the life of youth should not be neglected in the midst of educational, social, athletic or other preoccupations is indeed opportune.

Recalling the recommendation of the Malcolm Committee that education, whatever form it takes, should be related to the needs and circumstances of life, which for a vast majority of boys and girls means life spent in industry or commerce, the memorandum suggests that training for life implies a preparation for citizenship in the broadest sense, and that such training should be an integral part of the life of the school and of the curriculum in extension of work done in earlier services, the whole method and practice being linked with material services, such as fine school buildings, physical and recreative work, music, free meals, and also with the other social services. There should be an attempt in the last period of this portion of school life to ease the transition from school to the larger world outside through the creation of a club atmosphere, accompanied by corresponding modification of the curriculum.

While occupational guidance might be given in the schools by specially qualified teachers, no attempt should be made at direct training for livelihood except in schools directly concerned with technical training. In regard to part-time schools, the memorandum emphasizes that the main function is to continue the general education of the pupils, particularly in the broad aspects of citizenship; also that if the day continuation system is to be well and truly established, it must receive the wholehearted support of employers. It is to be hoped that the social conscience will finally reject the notion that if the young worker wants continuative education, it is his own business to seek it in the evening after a full day's work.

The particular difficulty which the small employer and small working unit present in this respect is recognized, as are those inherent in reconciling the claims of industry and education. The Council suggests that the position of the young person in industry should be regarded from the broad point of view of entry into employment, conceived as a continuous process moving by degrees from school life, through the sphere of youthful work, into the wider world of adult labour. It suggests the extension of the school medical service for the physical well-being of all minors, or at least medical examination so as to ensure that all juveniles are physically suited to enter the employment of their choice. Welfare work in industry should be closely related to the true needs of young workers; and to correct the excessive tendency to enter clerical occupations rather than trades the memorandum advocates the establishment of vocational training schemes based on expert sifting and guidance and the closest liaison with those responsible for apprenticeship.

The memorandum touches on a number of points in war-time experience such as the Essential Work Order, which may contain elements of permanent value for juveniles, and it directs special attention to three sections of the field common to education and industry of which little is heard: the need for a new outlook on the whole question of apprenticeship; the need for greater mobility of labour to meet unexpected changes in economic organization and location of industry; and the need for ensuring that those who have entered employment as 'learners', in the widest sense of the term, shall be equipped with that degree of adaptability which will enable them to meet the demand of any sudden turnover to new materials or fundamental revision of technique, as, for example, the changes which are bound to come as a result of the ever-increasing use of synthetic materials. These are questions of increasing significance, and it is essential that education and industry should work closely together in this field if the problems arising from them are to be solved. While deprecating pressure for too rapid development after the War, the Council would welcome and support any scheme calculated to secure the growth of a sympathetic understanding by teachers and educational administrators of the needs and problems of business and industry, and it is urged that such mutual relations should be fostered and encouraged.

The problem of youth in industry is essentially a question of entry into employment. The employer must consider the position of his young employees as an integral element in his management and organization. This will require the closest liaison and fullest co-operation between associations of employers and the trade unions to raise the entry into employment of juveniles to the status of industrial relationship. At the same time, education authorities must face the realities of the economic world which the juvenile will enter or has recently entered. The day continuation school may become a real meeting-ground between the two worlds of education and industry if it is administered, not merely as an educational service, but also as a means of recovery and refreshment for the young worker. Until, however, the problem of entry into employment is tackled by all concerned as part of industry as a whole, all elaborations of the machinery of choice of employment and vocational guidance will be vain and its products largely a matter of hazard.

HOUSEHOLD LIGHTING, HEATING AND VENTILATION

PAPERS read at two of the series of twelve meetings of the Royal Society of Arts recently devoted to "The Post-War Home: Its Interior and Exterior", have now been published (*J. Roy. Soc. Arts*, June 26). R. Fitzmaurice, principal scientific officer at the Building Research Station of the Department of Scientific and Industrial Research, gave a lecture on the lighting, heating and ventilation of the ordinary house. Many facts of topical interest relating to domestic use of fuel and power were included. Non-functional design of working kitchens leads to needless waste of lighting. Plans are reproduced of the distribution of daylight in ill- and in well-designed kitchens using the same ground-plan with redistribution of the same areas of glass in the walls.

All three subjects are intimately related. Large window areas or windows opened for ventilation may lead to excessive use of fuel for heating. It is estimated that about half the total quantity of coal raised in Great Britain is used for providing warmth in buildings, the remaining half being used for power and heat in industry. Although Germany has a colder winter and maintains better heating conditions in buildings, the consumption of coal for heating per head of the population is considerably less than in Great Britain. Less use of open fires and increased use of smokeless fuel help economy. From a graph reproduced it is shown that in the last forty years the price of coal in London has more than doubled.

The very variable nature of the British climate is an obstacle to the use of some highly efficient heating systems. For example, in the United States, Germany and the U.S.S.R. centralized heating of a whole district from a single boiler house is practicable. It is well known that large plants need to work as nearly as possible to their capacity to obtain a high order of running efficiency. In Great Britain, however, an installation capable of handling the heating load during our relatively limited cold weather would not be running nearly to its capacity over the greater part of the heating season.

Contributions to the discussion included one by R. Grierson, of the Northmet Power Company, who gave details for the small house. The lowest amount spent per year for heating services—coke, coal, gas and electricity—is about £7–£8 a year. The ordinary clerk or member of the lower-paid professional classes spends £15–£20 per year. Mr. Grierson gave full details for his own house, where £28–£30 a year is spent in heating its 12,000 cubic feet of space. For windows, a glass area of about 20 per cent of the floor area under normal conditions gives adequate natural lighting. A ratio of 12½ per cent makes a room definitely too dull.

The common type of German stove "is not a thing of beauty, but it does make for efficiency (45–70 per cent) and reduces the amount of heat energy lost up the chimney. If the Englishman gets 20 per cent of the heat energy of the coal into the room, that is to say, if he gets 12*s.* worth of heat out of £3 worth of coal, he is fortunate". In view of the national requirements in the economical use of fuel, these figures give food for thought.

A serious difficulty lies in the fact that the initial expense of the more efficient heating devices in a home is always greater than that of the inefficient. Similarly, a further wastage occurs in cheap roofing of houses. After the War of 1914–18, many cheap houses were built with roofs of tiles on laths. No lining of felt or other material under the tiles was used. As a result, the wind blows right through the loft space, the water in the cold storage tank is frozen in the cold weather, and the bedrooms are separated from an atmosphere which during last winter fell in temperature to 14° F., by about three quarters of an inch of lath and plaster ceiling. Such rooms—similar conditions also occur in living-rooms in cheap bungalows—are in effect fitted with panel-cooling; for it is found that on a hot day, if the temperature of the ceiling is only 10° F. below that of the room, the cooling effect is most marked.

Mr. A. F. Dufton, also from the Building Research Station, found that a gas fire, designed to burn 0·2 therm an hour (5–8 kw.), had to be used for two hours in all in order to warm a room for half an hour for breakfast, so long as the walls remained in their original condition, consisting of plaster and wall-paper. When, however, the heat absorption of the walls was reduced by lining them with wood panelling, half an hour of previous heating instead of the original one and a half hours sufficed.

The eleventh lecture in the series was given by Miss Helen Masters, who dealt with equipment and maintenance in the kitchen. While the heat requirements for cooking are here again of great importance, many other factors are involved. The mere accumulation of labour-saving devices, without organization of the work to be done, will not promote efficiency. Architects have sometimes given so much attention to reducing the number of steps to be taken in walking from one part of the kitchen to another that they have designed kitchens which are too small to work in at all.

SOUTH-EASTERN UNION OF SCIENTIFIC SOCIETIES

ANNUAL CONGRESS

THE South-Eastern Union of Scientific Societies held its forty-seventh annual congress at Guildford on July 25, a single day of sessions and excursions attended by seventy representatives and members.

A representative assembly to transact the business of the seventy constituent societies was held in the County School for Girls, at which Dr. J. Ramsbottom, keeper of botany at the British Museum (Natural History) was elected president of the Union for 1942–43; in recent years he has served the Union as president of the Botanical Section. The new treasurer is Sir Gordon Hearn.

"Fungi and the Biology of Man" was the title of Dr. Ramsbottom's presidential address. He stated the facts concerning struggle and survival in fungi, the existence of races and their immutability, parasitism and symbiosis in outline: points of similarity and of contrast in man were indicated. Man does not inherit acquired characters in a biological sense, but he is heir to every other change. No pure races of man exist and the theory of race and blood is nonsense. Competition or struggle is universal, but in symbiosis an equilibrium has been attained. Competition in modern man is, for the most part, sociological and not biological. The State is an organization and not an organism. War between States is not a biological necessity nor is it transcendental. Man has his full complement of biological characters at birth: they are immutable. His ideas, his theories, his wishes are developed through culture: they can be changed and therein lie the hopes of civilization.

At the sectional sessions the following papers were read: "Historic London under Fire", by E. Yates, who exhibited the deplorable damage to medieval buildings caused by enemy action; "Studies in the Variation of Native Plants", by Dr. A. R. Clapham, who advocated co-operation by botanical societies for the proposed new Biological Flora of the British Isles (*J. Brit. Ecol. Soc.*, 356; 1941); "Constructional Elements in the Physiography of the Southern Counties of England", by F. Owen Whitaker; "Spiders and their Life History and Habits", by E. A. Robins, who described a spider new to the British list, *Marinda aurantia*, the golden garden spider of America.

In the afternoon, Dr. W. St. Lawrence Finny, the retiring president, conducted a perambulation visiting and describing the history of St. Mary's Church, Guildford Castle and Museum, the Guildhall and its regalia and the Abbot's Hospital of 1619. Botanists visited the Compton district; geologists the Guildford brickworks and the Lower Greensand beds at Compton. It had been suggested that this Congress should be at Haslemere but, this being impracticable, the zoologists went there by train to see exhibits arranged in the Haslemere Educational Museum. There was a special exhibit of native flowers arranged by the Guildford Natural History Society, the officers of which organized local arrangements, and it was pleasing to see flowering specimens of our ancient woad, *Isatis tinctoria* L., now classed in most Floras as "a casual alien". T. DANNREUTHER.

THE ONTARIO RESEARCH FOUNDATION*

THE report of the Ontario Research Foundation for the year 1941 includes the report of the Director, the audited financial statement and a list of publications issued to December 31, 1941. During the year the work of the Foundation has been increasingly concerned with problems associated directly or indirectly with the War, and owing to the nature of much of the work in this field, as well as on problems of civilian production arising out of war-time restrictions on supplies of all kinds, a detailed reference to much of the work is not possible. The creation of centralized inspection laboratories has relieved the staff of much of the work in organizing and conducting laboratory work on behalf of the Inspector-General, but the securing and training for effective service of young graduates and technicians is a serious problem, although problems associated with personnel have been considerably reduced by the help of the local Registrar for Military Service. The quick and effective results which follow from full co-operation between men with long experience in industry and a scientific group actively engaged in research on the processes and materials of the industry have been demonstrated, and although it is clear that relations with industry require further development, the Director suggests that problems of the post-war period will afford a further opportunity for economical and effective work along these lines.

In the Department of Biochemistry, the Leather Laboratory has been used to varying extents by the Department of National Defence and the Inspector-General, and work on Service specifications has been continued in collaboration with the National Research Council. Preliminary tests have been made of a modified abrasion-testing machine for leather, and the production of organic acids from sugar by chemical and microbiological methods has continued. Methods for crude and refined lactic acid are now in use on a commercial scale in Toronto. A good deal of time has been devoted to a careful comparison of chemical and microbiological methods for determining the vitamin B_1 content of foodstuffs, including bread. In the Department of Agriculture, the Pathological Laboratory has investigated the infection of small experimental animals with *Ascaris lumbricoides*, and the same Department has now completed the greater part of its field work on the climate and main soil types of southern Ontario, and in co-operation with the Federal Department of Entomology has made a rapid survey of southern Ontario to determine the location and extent of nematode infection in oats.

In the Textile Department a reasonable balance has been maintained between testing, short-term problems and more fundamental research, and an investigation has been undertaken on the treatment of various synthetic fibres to overcome the serious drawback that they cannot be given a high degree of twist in their natural state without serious troubles developing in the knitting operation, and encouraging results have been obtained in collaboration with the Dominion Silk Mills, Ltd. Partly successful attempts have been made to obtain new products for processing wools from raw materials which are and will be available in Canada.

In the Department of Chemistry, the organic and metallurgical analytical laboratories have continued to operate on behalf of the Inspector-General and there has been a marked increase in the number of problems submitted by outside firms. The Gas Laboratory has given several months to the study of steaming of horizontal retorts at one of the plants of the Consumers' Gas Company, and in the Department of Metallurgy gauge-testing, heat-treatment, physical testing and metallography services have been available to Government departments and manufacturers, and the long-term research programme has largely been brought to a standstill.

AUTOMOBILE RESEARCH

A CONSIDERABLE amount of the work at the Research Laboratories of the Institution of Automobile Engineers is being done for Government departments, and since it is of a confidential nature may not be shown to a visitor. Nevertheless, at the recent inspection of the laboratories by members of the Automobile Research Committee and representatives of affiliated firms, there were several important investigations to be seen in actual operation. Usually, work of this nature arises directly out of the problems of the industry either in the form of an explicit question such as that of the fatigue strength of crankshafts, or from the more nebulous query as to whether aeration of the lubricant is a determining factor in the cause of bearing troubles, and these two cases are representative of the work being done at the Institution's Laboratory.

Three investigations into the aeration and frothing of lubricants were to be seen in operation on the above occasion. In the Chemical Laboratory, tests were being made to ascertain the frothing tendency of different oils at atmospheric pressure but variable temperature. In the Chassis Laboratory, a transparent bearing of plastic material has been arranged so that the behaviour of aerated oil can be observed, and it was of interest to note that, under the limited conditions permissible, the oil film at the pressure side was not ruptured. In the General Laboratory, a typical installation comprising a tank, aero-engine sump, oil cooler, pumps and filters has been set up in order to study the effect of high altitudes on the frothing occurring in an aircraft engine lubricating system. It is intended to run this at reduced pressures and to observe the amounts of froth formed in different parts of the system.

An investigation of a somewhat related character is that on the durability and wear of bearings, for which machines of two types have been developed. In these the test bearings are in the form of bushes cast or inserted in a steel shell and fitted as the big end of a connecting rod. As an extension of the work on these two machines, tests on full-size engine bearings are in prospect on another machine of special design by which an alternating load is applied by an external lever arrangement. This machine is in the experimental stage, and it was particularly interesting to observe the electric strain gauge developed for measuring the actual load applied to the bearing and the torsionmeter for the cyclic torque variation. Both measurements are made while the machine is in operation.

Fatigue tests on full-size crankshafts are carried on in machines which are arranged so that one throw alone is under test at a time, thus enabling a number of separate investigations to be carried out on one multi-throw shaft. The machines are of the constant-strain type, and the method of test involves the repeated application of a known deflexion to the crank under test. Piston-ring scuffing is being studied in a single-cylinder water-cooled engine, arranged so that the jacket temperature and quantity of lubricant supplied can be varied under control. A gas producer of the Government "Emergency" type is being used to supply gas to a converted petrol engine in an investigation to ascertain the power loss involved in the conversion, and the methods by which this loss can be made good.

In addition to such work as is described above, the Laboratory staff is actively engaged in the preparation and circulation of abstracts of current technical literature bearing on matters affecting the automobile industry. Inquiries for technical information are dealt with by the library staff; the library contains a valuable collection of text-books, periodicals, pamphlets, research reports and reference volumes, thus providing the basis for the information service which supplements the research work of the Committee.

EARTHQUAKE ACTIVITY IN NEW ZEALAND

AN earthquake of considerable intensity shook the southern part of the North Island of New Zealand at approximately 11.35 a.m. local time on August 2. The epicentre of the shock was considered in New Zealand to have been some fifty miles from Wellington. The country districts most affected were Manawatu and Wairarapa, where the damage was considerable, though not on the same scale as at Wellington. The shock was estimated to have been as severe as that on June 24 (Nature, July 4, pp. 18–19) though, according to human perception, it was of shorter duration. During the June earthquake damage was done to post office and power lines and water supplies, and many buildings were cracked. During the August shock hundreds of chimneys fell, many windows were broken and several of the buildings damaged in June were so severely shaken that it is likely they will have to be demolished. Some streets were temporarily closed to traffic and the City Engineer estimated that the damage in Wellington may run into hundreds of thousands of pounds.

The Dominion Observatory at Wellington has just (1942) published Bulletin No. *S*-64, "The Seismicity of New Zealand", by R. C. Hayes, which divides the islands into four seismic zones having marked differences in seismicity. Bastings has stated that the seismicity of New Zealand as a whole is high compared with other countries, due mainly to the relatively large number of earthquakes of the semi-destructive type. The seismicity of any region is governed by both the maximum intensity of the shocks which occur and the frequency of the earthquakes. In the work of Hayes, the relative seismicity is obtained by multiplying the average number of shocks per decade (1835–1940) in the area of Rossi-Forel intensity 10 by 10, the average of intensity 9 by 2, and adding these to the average number of intensity 8. Freeman's work had previously shown that earthquakes of R.F. intensity 9 are twice as destructive as those of intensity 8, and those of intensity 10 are ten times as destructive as those of intensity 8.

The average number of earthquakes per year (1921–40) is considered separately. Whenever earthquake swarms such as that in the Taupo region in the latter half of 1922 occur, only the stronger ones have been considered. On these facts, the four regions are: (I) The northern half of South Island and the south-eastern half of North Island with Cook Strait in the centre. This has an average of 97·8 earthquakes per year, and a relative seismicity of 11·5; (II) the central portion of North Island, average 23·0 earthquakes per year and relative seismicity 1·1; (III) the whole of the southern half of South Island, average 12·1 per year and relative seismicity 0·1; (IV) the extreme northern tip of North Island, average 1·1 earthquakes per year and relative seismicity 0·0. In region I, the strongest shocks tend to congregate towards the east and south-east though the north-western part has the highest frequency for moderate or small shocks. The difference may be due to differences in the strength of crustal materials. In region II Taranaki is liable to semi-destructive shocks at infrequent intervals, "near" Auckland may have had violent shocks during 1835–36, and New Plymouth in 1819. In region III one semi-destructive shock between Mount Cook and Lake Wanaka has been definitely recorded though heavy shocks in the west coast sounds area have been mentioned in 1792, 1810 and 1826–27.

Earthquakes within about 10° of Wellington during May 1942 numbered 12. The greatest had intensity 4 (Rossi-Forel) on May 10, near Whakatane, and one on May 27 may have had intensity 3 at Upper Takaka. Two shocks on May 7 and May 21 respectively were felt at Rotorua. Additionally, five distant earthquakes were registered by the seismographs at Wellington, Christchurch, Auckland and Arapuni according to the provisional Bulletin *P*-123 published by the Dominion Observatory at Wellington.

ORIGIN OF COSMIC RAYS

A NEW hypothesis of the origin of cosmic rays and reports on its experimental testing in India and elsewhere are published in the *Physical Review* (61, 397 and 407; 1942) by R. A. Millikan, H. V. Neher and W. H. Pickering. While retaining the fundamental basis of nuclear physics theories and transformations of rest mass into other forms of energy, former suggestions are reversed. The sun's heat is assumed to correspond with atom building going on in its interior, whereas cosmic rays are due to the complete annihilation process going on in interstellar space. The transformation of the rest mass of the atoms into cosmic-ray energy is postulated as *complete* instead of partial.

When the postulates are used, five definite cosmic-ray bands are predicted, each reaching the earth in a particular latitude, and four plateaux of unchanging cosmic-ray intensity, these plateaux being delineated by the latitudes of entrance of the successive bands. The bands are named as (i) a silicon band of energy 13·2 Bev., (ii) an oxygen-nitrogen band of mean energy 7·1 Bev., (iii) a carbon band of energy 5·6 Bev. and (iv) a helium band of energy 1·9 Bev.

To test these predictions it was necessary to measure directly *vertical* incoming cosmic-ray energies as a function of latitude. India is the most suitable place in the world for the most significant of the tests. While in India it takes 17 billion-volt, vertical, charged-particle rays to break through the blocking effect of the earth's magnetic field at the equator, about 13 billion only suffice on the other side of the earth in Peru.

A comparison of theory and experiment was made possible largely through generous support of the research by the Carnegie Corporation of New York, the Carnegie Institution of Washington and the India Meteorological Service. The results so far attained are the detection of the silicon band and the joint nitrogen-oxygen band, with less definite observation of the carbon and the helium bands. The predicted values for latitudes and order of intensity are approximately of the same value as the observed. At least three of the four plateaux of constant cosmic-ray intensity were observed.

In the second paper, by Neher and Pickering, experimental details are given, although full description of the apparatus appears in the *Review of Scientific Instruments* under the title "A Cosmic-Ray Radio Guide" (13, 143; 1942). This instrument is a miniature radio-transmitter recording barometric pressure and atmospheric temperatures as well as the Geiger counter observations. By its aid, Geiger counter and electroscope observations were compared. The counter was found to give results very close to those of the electroscope and of comparable accuracy. When two or more counters are arranged as a cosmic-ray telescope, the radiation from a selected part of the sky only is recorded. Thus the energies recorded are delimited with considerably greater accuracy than by the use of the electroscope.

FORTHCOMING EVENTS

Tuesday, August 25

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 2.30 p.m.—Conference on "Civil Engineers and the Building Industry" (to be opened by Prof. C. E. Inglis, F.R.S.).

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant to the Advisory Officer in Plant Husbandry, and an Assistant Lecturer in the Department of Bacteriology—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow (August 28).

Assistant to the Chief Research Officer of the Mental Disease Research Department—The Secretary, The University, Birmingham (September 1).

University Chair of Chemistry, tenable at the Royal Cancer Hospital—The Academic Registrar, University of London, Richmond College, Richmond, Surrey (September 1).

Physical Chemist and a Mineralogist or Geo-chemist for research work into materials and processes of the ceramic industries—The Director of Research, British Pottery Research Association, Queens Road, Penkhull, Stoke-on-Trent.

Graduate (man or woman) in Science or equivalent in Engineering, and a Graduate (man or woman) in Science including Biology, and able to assist in General Subjects, at the Mexborough Schofield Technical College—Mr. E. B. Stockdale, Education Office, Mexborough, Yorks.

College of Science Physics Dept.

THE MAKING OF A PHYSICIST

THE physicist, like the poet, is born and not made. Neither can be produced, on demand, by any system of training. In each category we have to make do with what Nature, in her wisdom, supplies, and the number in each category is extremely small. As regards the physicist, statistics have recently been given by Sir Lawrence Bragg in a discourse on "Physicists after the War", delivered at the Royal Institution (NATURE of July 18, p. 75). If, following Sir Lawrence, we define a good physicist as "a man capable of independent thought, with a flair for his subject", then in Great Britain "about one good physicist is bred per year per million inhabitants". Assuming that each has a working life of thirty years, this gives us a total of some fifteen hundred professional physicists, an estimate which agrees fairly closely with the records of the Central Register. It is interesting to note that a preliminary survey made some months ago in the United States in preparation for its war effort yields substantially the same proportion. It is possible that a few potential physicists escape the widely flung net of our scholarship system and remain "mute, inglorious Miltons", and it is certain that a small number, owing to accidental circumstances, find themselves engaged as chemists or engineers, but it is unlikely that the grand total of available physicists falling within the scope of Sir Lawrence's definition can be much increased. The total falls much below our present war-time requirements, and well below the requirements of a post-war society in which science will play its proper part.

Fortunately, the situation is not quite so desperate as it seems. The standard set by Sir Lawrence's definition is a high one—there can be few, if any, other professions which make such rigorous demands of their membership—and many of the tasks for which physicists are required, both in the present emergency and in the normal routine of industry, can be very adequately performed by men and women less well gifted. In an attempt to increase the number of young physicists for war purposes, the Board of Education last summer made the experiment of offering State bursaries on a generous scale to all boys and girls reaching a definite standard in physics and cognate subjects in the Higher School Certificate examinations. This has resulted in a very substantial increase in the size of the physics classes in the universities and colleges. The experiment is too recent to allow of a final pronouncement ; a preliminary survey makes it doubtful whether it will add materially to the limited number of "good physicists". There is, however, no doubt whatever that it is adding substantially to the numbers available for the more routine but no less important posts for which originality of a high order is not a *sine qua non*. It may be safely predicted that there will be many such posts in post-war industry ; and these new recruits form a valuable reinforcement to our scientific potential. Their existence will enable us to assign the always strictly limited number of men with a real flair for research to work which they alone can do.

Even with this addition, our assets, in scientific man-power, are small. It is worth while, even in war-time, to spend some sustained thought on the best methods of training and utilization. For the physicist, indeed, the problem is one of particular urgency. To meet the immediate demands for young physicists in the war effort, university courses in physics are being not only curtailed but also rather heavily biased towards specific parts of the subject of immediate application. Thanks to the wisdom and foresight with which the "Hankey training scheme", as it is generally called, has been planned and administered, the courses remain recognizably courses in physics. Broad foundations are being laid, upon which further training can be based when the present emergency is over. It must be recognized, however, that most of the young physicists now hurrying from the universities to take their place in the national effort are far from being fully equipped for the scientific work which they will be called upon to carry out, we may hope, in the post-war reconstruction. If the irreplaceable asset represented by their skill and intelligence is to be used to the full their education must be completed, and their training for new tasks undertaken. There is reason for believing that this necessity has not escaped notice in official circles. Since arrangements, to be effective, must precede the demobilization of the men and women concerned, discussion of the best methods for the education and training of physicists is one of immediate urgency, and the Institute of Physics has been well advised in placing the subject well to the fore on the agenda of its Planning Committee. A memorandum on the subject, prepared by Dr. H. Lowery, has already been circulated to members of the Institute and others interested in the subject. This, together, no doubt, with the very interesting and novel views expressed by Sir Lawrence Bragg in the lecture to which reference has already been made, will serve as the basis for a discussion which the Institute is hoping to hold in the early autumn.

Without venturing to anticipate the results of such discussion, it may be useful to direct attention to a few general principles, since general principles have an uncanny habit of getting mislaid when attention begins to focus itself on details. In particular, the fundamental distinction between education and training is one which is very apt to become blurred. (There is evidence of this in reports of recent, otherwise inspiring, speeches of the President of the Board of Education.) The distinction is of particular importance when dealing with the making of a research physicist. Though his discoveries sometimes lead to considerable advances in engineering, the research physicist is not a kind of super-engineer; in fact, industrialists who try to employ him on engineering work usually find him distinctly disappointing. His real affinity is with the creative artist, and his value to the community lies in the spark of originality which he brings with him into the world. To fan this spark into a flame, to feed it with appropriate fuel, or, to drop the metaphor, to assist the student to develop his full stature as a physicist is our first and most urgent task. Training for a more specific task should follow, not accompany, this process of education. Since the distinction between the "good physicist" and what we may call the routine physicist is one of degree rather than kind, it would appear that the same process should also be applied to the latter, up to the limits of his capacity.

Education, at its best, is a very personal matter, not lightly to be intruded upon by outsiders. The student gains more from contact with the mind and personality of his professors than from their formal instruction. That is one reason why the university department with its happy blend of teaching and research embodied in the same individual affords, on the whole, such an excellent cultural medium for the embryo physicist. There is, of course, no room for complacency. Lacking the centuries of experience which have gone to the perfecting of, say, the teaching of the classics, and faced with the difficulty of teaching a subject which is expanding at an enormous rate, it is not to be expected that physicists should have yet discovered the best ways of presenting their subject. In one particular a grave error has undoubtedly developed. In the attempt to keep pace with the rapid growth of the subject, far too heavy a load has been placed upon the shoulders of the 'honours' physics student. From the moment when he is identified as a possible scholarship candidate to the moment when he emerges dazed but triumphant as an honours graduate, his time has been completely absorbed in his subject. He has not had leisure in which to grow up. "He has not", to quote Sir Lawrence Bragg again, "learnt to mix with other people, and form one of a team, to take responsibility, to trust his own judgment, and have initiative. . . . The industrialist compares him unfavourably with boys who have worked their way up, and become men of the world."

The picture is a little overcharged, and it would be possible to quote many exceptions. That there is much substance in it cannot be doubted. Considerable doubt may be felt as to the efficacy of Sir Lawrence's suggestion that the problem could be solved by interpolating a six months apprenticeship to industry for all honours students between their leaving school and entering the university. Apart from the fact that many educationists would regard a definite break in the student's career at this stage as being undesirable in itself, there is the risk that this preliminary apprenticeship might lead the student to regard his subsequent studies as a training for industrial service, rather than as an education in physics; and to be a little impatient (anyone who has had to teach physics to medical or engineering students will know the symptoms) of matters of no obvious practical or industrial importance. But it is precisely because the physicist, for the sheer love of the subject, has studied many matters of no obvious practical importance that he is able to make his unique contribution to industry. The fact that the charge of immaturity is not, as a rule, levelled at the statesman, barrister, physician or economist who graduates through the universities of Great Britain shows that there is little wrong with the environment itself. The trouble is that, owing to the pressure of work, the physics student has been largely isolated from this environment. The remedy is to lighten the load, and so give him the opportunity to take an adequate part in the non-academic but formative activities which are such a valuable part of university life.

This necessary reform cannot be carried out in isolation—no university will willingly admit that its honours standard is less exacting than that of its neighbours—but it should not be beyond the powers of the universities as a whole to work out an agreed solution. As regards the schools, much might be achieved by the elimination of the present competitive scholarship examinations and the substitution of a system on the lines of the new State bursaries. If every pupil who reached a certain well-defined standard was assured of a university education if he desired it, much of the stress which hampers the real education of the present scholarship candidate would disappear. Any extra expense in which the State might be involved would yield a rich return.

The training of the young graduate for research is generally provided for by allowing him to spend a year or two in research in the university. The system has grown up quite fortuitously, but its value has not been seriously challenged by the industrialist. It would probably be difficult to devise anything better. One proviso, however, must be made. It should be clearly kept in mind by the student, and particularly by the director of research, that these years are years of training. Their object is to produce a research physicist and not a series of "communications". The neophyte should be given a problem which will test his powers, and considerable latitude in handling it. The freedom to make one's own mistakes, though not formally embodied in any charter, plays a valuable part in the process of training. The temptation to use the trainee as an observer in other people's researches should be firmly resisted, and the department should be satisfied to be judged primarily by the quality of the men it produces, rather than by the quantity of original papers it turns out. In this connexion the methods of Sir J. J. Thomson, the greatest trainer of research physicists the world has yet seen, are worth close study.

On the psychological or personal side, it must be confessed, the position is not quite so happy. While the routine physicist, as a rule, settles down quite readily in industry, the research physicist only too often both experiences and creates a certain irritation. The industrialist complains that his new recruit has far too good an opinion of himself. The young physicist, eager to prove his worth and to give of his best, finds himself enmeshed in a system of regulations and restrictions which appear to him to have been specially designed to prevent him from getting on with his work, and very often called upon to do things which seem to him of negligible importance. There is need for adjustments on both sides, if physics is to make its maximum contribution to the welfare of society. Not only must the physicist learn to fit himself for industrial conditions—industry must also learn to adjust its conditions to the physicist. Goodwill is not lacking on either side. The physicist in industry is as keen upon his work, and as rightly convinced of its value, as his university colleague; while our best industrial concerns are genuinely proud of their research departments and anxious for their welfare and efficiency. What is needed is a better understanding of the conditions which are essential to the creative artist (let us strike this note again, for it is the keynote in the situation) if he is to give the best of which he is capable. It may be admitted that the problem of making the necessary adjustments in organization is not an easy one for the industrialist; it requires courage and vision, qualities in which the great industrialist should not be lacking. Progress has been made, particularly in the United States; and some of the larger industries in Great Britain are at least moving in the right direction, with Government research, on the whole, lagging sadly in the rear.

The problem of the best utilization of our limited scientific capital involves more than the provision of the best methods of educating and training the scientific worker himself; the conditions under which his special gifts can find their amplest outlet must simultaneously come under review. It is only as the two aspects of the problem are studied in conjunction that the right solution will be attained.

THE HIPPOCRATIC MYTH

Disease and the Social System

By Arthur Guirdham. Pp. xvi+240. (London: George Allen and Unwin, Ltd., 1942.) 10*s*. 6*d*. net.

It is a pity that Dr. Guirdham does not value his ideas more highly, since many of them are exceedingly good. To recapture the primordial Hippocratic vision, in which specific disease is seen in relation to the total personality, is an idea worthy of serious handling. But the author's staccato, rather malicious, style fails to clothe his ideas with persuasive interest. The satirical mood is convincing only when the author is truly gripped by his vision. But for satire to be effective the cheap sneer must at all costs be excluded. In this work even the chapter headings are not free from this curious vulgarity as, for example, the caption "Lead Kindly Light", above a chapter in which current medical teaching is held up to ridicule.

In regard to his main theme Dr. Guirdham is clearly right when he tells us that we have lost the true perspective, that we no longer see the total human being in our teaching of medicine, but have apportioned man into arbitrary fields for specialists. It must be admitted, however, that the idea was presented better by Plato and with greater economy of argument. In the Dialogues, for example, we find: "But Zamolxis . . . says further that as you ought not to attempt to cure the eyes without the head, or the head without the eyes, so neither ought you to attempt to cure the body without the soul: and this, he said, is the reason why the cure of many diseases is unknown to the physicians of Hellas, because they are ignorant of the whole, which ought to be studied also; for the part can never be well unless the whole is well." Plato then proceeds to affirm the importance of psychotherapy as the fundamental medical approach. "For all good and evil," he asserts, "whether in the body or in human nature, originates . . . . in the soul, and overflows from thence, as from the head into the eyes. And, therefore, if the head and the body are to be well, you must begin by curing the soul; that is the first thing." In this, the very foundation of the true medical point of view, Dr. Guirdham's illumination has not the clear integrity of the Greek vision whence his inspiration is admittedly drawn. Indeed, he reserves his worst venom for modern psychotherapeutic methods, without himself providing any better means for grappling with the problems of the soul than that of masterful hortation.

If Dr. Guirdham's main contention can be substantiated, namely, that the incidence and character of disease have shifted in the direction of the autonomic, endocrine and psychical fields, then the problem of disease in the future will surely demand the fullest possible research into the fundamental psychological determinants of human nature. The historical patterns which determine the character of our social system are part of our psychological inheritance and, since the individual is the unit of society, it must be in the realm of the individual psyche where the tyranny of the pattern can be fought. Logically, therefore, if Dr. Guirdham were to take his ideas seriously, he would be advocating far-reaching research into the nature of the unconscious. He would also insist upon the teaching and practice of psychotherapy as an integral function of the health centres which, in the near future, will determine the character of medical practice. It is just because he breaks his lance against the social windmill that the author fails to convince either himself or his reader that he has any effective remedy for the ills of mankind. His snap judgments and ineffectual satire might even be regarded as the product of Quixotic frustration. He condemns modern man for chasing vague and nebulous goals, but is not the social system, which he himself attacks, the most nebulous goal of all?

The book abounds with dashing generalizations of which the following is a fair specimen: "Psychiatrists should also be historians. The German race for two thousand years have maintained a carefully conceived national policy of brutality, fraud, opportunism, cunning and terrorism. They have lived in the continent which above all others has been throughout the centuries a pioneer in civilization." For how long has the German race been a nation with a "carefully conceived national policy"? What student of history would put his name to such an assertion? Moreover, one of the main reasons for our inability to prepare against the German cataclysm was because we could not believe that Germany could ever be guilty of destroying the very civilization of which she herself had always, and rightly, claimed to be a pioneer. Our present confusion of mind in regard to post-war problems is not unrelated to this suicidal split in German psychology. It is difficult to accept that the upper half of a nation can be civilized while the lower half remains sunk in barbarism. But are we also completely civilized from top to toe? Without the historico-psychological point of view, what hope is there for a fair appraisal of the problems of our time?

Yet, in spite of the author's exasperating recklessness of statement, his book is also rich in good ideas, and if mental stimulation were all one required it would serve remarkably well. H. G. Baynes.

TEXT-BOOKS OF ACOUSTICS

Acoustics

By Dr. Alexander Wood. (The Student's Physics.) Pp. xvi+588. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1940.) 27*s*. 6*d*. net.

A Text-book of Sound

Being an Account of the Physics of Vibrations with Special Reference to Recent Theoretical and Technical Developments. By Dr. A. B. Wood. Second, revised and enlarged, edition. Pp. xvi+578. (London: G. Bell and Sons, Ltd., 1941.) 30*s*. net.

THERE can be no doubt that British text-books of acoustics are the finest published in any language. Most of the best advanced text-books in physics now come from the United States. General text-books in acoustics are still the exception, and the British product is best. For this reason, Dr. Alexander Wood, in writing the latest text-book, set himself a difficult task. The result is completely successful. Modestly stating that the book "makes no claim to originality", he gives the clue to its excellent qualities by explaining that he wrote "primarily for the interest of writing".

The treatment throughout is comprehensive. Theory, experiments and applications are given with references to original sources. Many excellent diagrams, graphs and photographs are included. As the history of each branch is given more fully than in any other British text-book, the student is helped to realize that in science the branches of a subject are developed gradually, that discoveries in another field may suddenly provide just what was wanted to help in the subject of his own special interest. Because of spasmodic developments, the historical presentation of a subject may be too slow for the 'go-getting', examination-pursuing student. The method presents, however, the facts of how a subject develops and of how his own researches will go if he follows any but the path of safety-first.

Much of the beauty of physics lies in the linking together of such diverse phenomena, affecting different sense organs, by a few simple general principles. Vibrations and wave motion unite sound with mechanical, optical and electrical phenomena. The author neglects no opportunity of developing the relationships. For example, the chapter on diffraction includes an experiment in acoustics analogous to crystal 'reflexion' of X-rays. Two minor suggestions may be made. Students would be helped by a collection of problems (a few examples are given in the text) and by an annotated bibliography of the standard reference works in acoustics, including the journals specially devoted to the subject.

Dr. A. B. Wood's "Text-book of Sound", first published in 1930, has since been twice reprinted and now appears in a revised and enlarged second edition. The new edition preserves all the excellences of the old, and there is newer material in such branches as supersonics, hearing, noise and various technical applications. Where the additions do not justify resetting the text, new references to original sources are given.

If comparisons are made, the order of increasing fullness of treatment is Richardson's "Text-Book of Sound", followed by A. B. Wood's, with Alexander Wood's outstandingly mature work giving the fullest treatment of the subject available in English.

W. H. George.

HALLEY'S COMET AND ITS IMPORTANCE*

By PROF. H. C. PLUMMER, F.R.S.

THIS lecture coincides with the bicentenary of Halley's death, for he died, the second Astronomer Royal, on January 14, 1742, at the age of eighty-five. To this office he succeeded Flamsteed, after holding the position of Savilian professor of geometry from 1703 until 1720.

The quality for which Edmond Halley, Hon. D.C.L. of the Queen's College in the University of Oxford, was most remarkable was beyond any doubt his versatility, which ranged far beyond the subjects which are prescribed for this lecture. Thus in the Breslau Tables he made the first contribution of fundamental importance to the science of vital statistics. He was a post captain in the Royal Navy. He gave effective advice to the Emperor on the fortification of Trieste. Here it may be interesting to notice that in this task he was following a tradition which can certainly be traced back to Galileo who, as professor of mathematics at Padua, lectured on the subject of fortification and published a textbook on it.

But here I shall turn to what is probably the most important side of Halley's astronomical work, his discussion of the orbits of comets. This subject has not been dealt with at any length in these lectures, and it is related to a matter which might be regarded as Halley's greatest achievement, and perhaps the most difficult: the tactful handling of Newton and the production from him of his supreme effort.

The appearance of a great comet is an infrequent event, occurring at very irregular intervals. Year by year several comets, say from five to ten, are seen and observed. Some of these even become visible to the naked eye, but they are rarely conspicuous objects. The last comet which earned the title of 'great' was seen in the year 1882. It was notable as the first comet to have its portrait taken. The phrase is appropriate because the portrait was taken by an ordinary professional photographer with an ordinary portrait lens in an ordinary camera strapped to an equatorial at the Cape Observatory. The event signalized the advent of the dry plate, which was destined to re-arm the astronomer with a new weapon. Not that this was the first use of photography in astronomy—it had been employed for several years in the new Oxford Observatory—but it marked the introduction of a far simpler process by a striking example.

In the sixty years which have elapsed since that date, only two comets have excited popular attention in the northern hemisphere, though several have provided notable objects for photographic study. Both of these comets were seen in the year 1910. The first came unheralded, and many will remember its beautiful and impressive appearance in the February of that year. The approach of the other had been followed since the preceding autumn, when it was first detected well within 10′ of its predicted place. For this was Halley's celebrated comet returning from its long journey after seventy-five years absence. Because the nearest approach to the sun took place in April, the appearance of the comet was disappointing in this latitude. But in tropical countries the conditions were more favourable and the spectacle was impressive enough. The February comet will need no further remark, but that it illustrates one point. In order to establish the identity of a comet, much more is necessary than its appearance near an expected date. For the two brightest comets in the last sixty years were separated by no more than three months in the time of perihelion passage.

The history of Halley's Comet has been traced back over more than two thousand years. Of this long period barely the last third is covered by useful European observations. Happily in this instance the balance has been redressed by recourse to the East, for Chinese records have proved invaluable. This is true even in the middle of the period, when Arabian astronomy was in the ascendant. The Arabs, like Ptolemy, do not seem to have paid much attention to comets; any observations made by them seem to have escaped notice, if indeed they were made at all.

Thus the story of a single comet represents a section of astronomical history. In the ancient world perhaps Seneca came nearest to a sensible view of comets, but nothing of real scientific value was possible before the fifteenth century, when the Viennese school became active in astronomy. Its most distinguished product, Regiomontanus, observed the comet of 1472 and wrote on the subject. But his work on comets was not published during his short life-time. To him is doubtfully[1] assigned a limiting parallax which places comets beyond any reasonable boundary of the atmosphere. This deserves notice as an early result of observation. The next step was made by Tycho Brahe, who from observations of the comet of 1577 narrowed the parallax to 1°, and so placed comets beyond the moon. It remained for Kepler, observing the comet of 1607 (Halley) to go further and assign the orbit to planetary space. Thus the seventeenth century started with a fair knowledge of the region in which comets are located. This does not mean that so much was universally accepted: Galileo, for example, entertained ideas which were quite retrograde, even after 1618, when three bright comets appeared.

If sound views on distance were slow in forming, naturally ideas on the nature of cometary motions were even more backward. Tycho supposed the motion circular, and Kepler, confronted by a problem apparently quite unlike that presented by the planet Mars, conjectured motion in a straight line. We shall notice later on that a much sounder view was taken far nearer home. Hevelius in his "Cometographia" (1668) suggested a parabolic orbit, but this was a vague guess which had been anticipated by Borelli (alias Mutoli) even earlier (1664). Dörfel, who had been a pupil of Hevelius, arrived by a more legitimate path at the same conclusion as his master, by applying a geometrical discussion to the observed places of the great comet of 1680. But this work, whatever its merit, came too late to have any real importance. Astronomy was already on the brink of its most momentous epoch, and the true solution of the problem was now so near at hand, and as we now know so inevitable, that more or less fumbling guesses lose their interest. The law of cometary motion was never discovered in the sense that Kepler discovered the laws of planetary motion. The knowledge came simply as a by-product of Newton's work on gravitation.

Towards the end of the year 1680 the comet already mentioned was discovered by Gottfried Kirch at Coburg in Saxony. Few observed it before it reached perihelion; afterwards there were as many observers as astronomers living[2]. This was the comet observed and discussed by Dörfel, a pastor at Plauen in Saxony, in a work which has become exceedingly rare and inaccessible. It was also observed by Newton, and thus helped to revive in him an interest in astronomy which had been dormant for many years. But Newton's experience was not altogether happy, as the following extract from a letter indicates.

---

* Halley Lecture delivered at the University of Oxford on May 25.

> Newton for Flamsteed (through Mr. Crompton).
> "Cambridge, Feb. 28, 1680.
>
> "I am further suspicious that the Comets of November and December which Mr. Flamsteed accounts one and the same comet were two different ones, and I find Cassini in a copy of a letter of his which Mr. Ellis shewed me is of my mind. . . ."

Of course, Flamsteed was right and Newton was wrong, though he erred in respectable company. But the sequel is important enough to warrant this quotation.

> Newton to Flamsteed.
> "Trinity College, Cambridge.
> "Sept. 19, 1685.
>
> "Sir,
>
> ". . . I have not yet computed the orbit of a comet, but am going about it, and taking that of 1680 into consideration, it seems very probable that those of November and December were the same comet . . ."

It was convenient to forget the letter of five years before, but fortunately we are not concerned with that aspect of the case. By this time the acid stimulus of Hooke and the urgency of Halley have done their work, and Newton had already made substantial progress in the preparation of the "Principia". But though the principles were established and the complete design no doubt formulated, the necessary details for calculating the orbit of a comet were clearly not worked out before the end of 1685.

The outcome of these hectic months in Newton's life is well known. In the "History of the Royal Society of London"[3] it appears thus:

> "1687. April 6, Dr. Gale, vice-president, in the chair.
>
> "After the minutes of the last meeting were read, the third book of Mr. Newton's treatise *De Systemate Mundi* was produced and presented to the Society. It contained the whole system of celestial motions, as well of the secondary as primary planets, with the theory of comets; which he illustrates by the example of the great comet of 1680–1, proving that, which appeared in the morning in the month of Nov. preceding, to have been the same comet, that was observed in Dec. and Jan. in the evening.
>
> "Dr. Gale reported that he had lately received a letter of thanks from the authors of the *Acta Eruditorum Lipsiensia* for the *History of Fishes* sent them as a present from the Society."

In view of the importance of the occasion, the stress laid on a detail in cometary history may seem exaggerated, but is nevertheless significant. Similarly, there is a reason for repeating another single item from the minutes of the same meeting. The publication of the "History of Fishes" had gone far to deplete the funds of the Society and made it difficult to carry out another costly undertaking. How Halley stepped into the breach and took on himself the liability for the production of a work which owes so much to his encouragement for its existence is a familiar story. It is impossible to conjecture what the world would have lost if Halley had not lived. He had done more than anyone else to inspire the "Principia", he had kept an over-sensitive author to his task, and now he undertook its publication. The nature of a fourth service is still to be seen.

Several years passed, and Newton was within a year of leaving Cambridge, when more is heard on the subject of comets. The latest development can be given in Newton's words:

> Newton to Flamsteed.
> "Cambridge, Sept. 14, 1695.
>
> "Sir,
>
> "When I received your last, Mr. Halley was with me about a design for determining the orbs of some comets for me. He has since determined the orb of the comet of 1683 by my theory; and finds, by an exact calculus, that it answers all your observations and his own to a minute. . . ."

The reference is clearly to the comet of 1682, now known as Halley's, but the great man was ever a little careless about dates. This work on which Halley was already engaged only saw the light ten years later. His time was fully occupied. Between 1696 and 1698 he was deputy controller of the mint at Chester. In the four years after that he was almost continuously at sea in command of H.M. Pink, the *Paramour*, first in making the magnetic survey and then in charting the English Channel. Next year (1702) he made two voyages to the Adriatic, to advise a foreign Government on the fortification of Trieste. At last, in 1703, he became Savilian professor of geometry, in succession to Wallis, and could look forward to a time of comparative leisure. What he did was to finish the work on comets, and when that was published he produced in the following year the edition of Apollonius, for the purpose of which he had learnt Arabic. His activity at this period of his life was certainly amazing.

The paper[4], "Synopsis Astronomiæ Cometicæ", in which Halley communicated the results of his cometary researches to the Royal Society, is a model which can be commended to the attention of those authors who find that scientific societies are unwilling to grant all the space which they think is due to them. For this memoir, the importance of which has been universally recognized by laudatory epithets*, fills less than eighteen small quarto pages of fairly large type. There is a historical introduction (3 pp.). A single page contains the kernel of the whole, a table giving the parabolic elements of twenty-four comets; as Halley says, "Immensi pene Calculi fructum, exiguum quidem . . . munus." Then follows a kind of Barker's Table† (4 pp.) with a description and example of its use occupying about the same space. It can be inferred how much room was left for a discussion of the results.

In this paper purely parabolic motion is assumed throughout. The orbits are determined by Newton's methods. Whatever was not to be found or not understood in the "Principia" would naturally be supplied by Newton, for the two men were in close contact in this work, as the letter of 1695 shows.

---

* For example, "epochemachend" (Mädler); "ces travaux si brillants et si neufs" (Delambre).

† The original Barker's Table was first published in 1757.

There has never been any dispute about their shares in the result, not need there be. Newton provided the methods, which from a practical point of view left ample room for improvement*, and Halley did the work of calculation.

PARABOLIC ELEMENTS OF 24 COMETS. HALLEY

Date of Perihelion Passage	Ascending Node	Inclination	Motion	Perihelion Longitude	Perihelion Distance
1337 June 2 6 25	84° 21′ 0″	32° 11′ 0″	R	37° 59′ 0″	0·40666

A glance at the table of parabolic elements, which is reproduced here in a slightly modified form (in the original the longitudes are naturally expressed in the conventional Zodiacal signs), is enough to show the main result. The orbits found for the comets in the years 1531, 1607 and 1682 are strikingly similar. For this fact there are two possible explanations. Either three different comets follow the same path at nearly equal intervals of time (seventy-six or seventy-five years), or else it is one and the same comet describing an elongated elliptic orbit which would differ little from a parabola in the neighbourhood of the sun. Between these alternatives the question must have been one of probability. More recently, groups of comets with similar orbits have been found. But when the whole number of known orbits is no more than a couple of dozen and the difference in period is only a year, the choice looks simple. Still there is that difference, and therefore there is an element of risk. The reason for it Halley quite rightly attributed to the disturbing influence of the planets.

When the paper was reproduced with additions ten years after the author's death in 1742, in "Dr. Halley's Astronomical Tables", more confidence is shown in the identity of the three comets. Motion in a highly eccentric ellipse has been investigated. The mean distance assigned is $a=17{\cdot}8635$, the eccentricity (in Halley's sense) is $ae=17{\cdot}2810$, and therefore the eccentricity (in our sense) is $e=0{\cdot}9672$, a figure which does in fact lie between the osculating values in 1607 and 1682. Changes in the inclination and in the positions of the node and perihelion are unimportant because the observations of Apian in 1531 and Kepler in 1607 are too rough for any certainty, but the effect of perturbations is pointed out. Halley could not calculate the effect of perturbations on the period with any accuracy, but he estimated the influence of Jupiter fairly shrewdly. For he predicts the next return "circa finem anni 1758 vel initium proximi", and in the circumstances this is a very good approach to March 1759, the actual date.

It is only in this second version (1752) that two noteworthy passages occur. The first, which is famous, runs:

"Quocirca si secundum prædicta nostra redierit iterum circa annum 1758, hoc primum ab Homine Anglo inventum fuisse non inficiabitur æqua Posteritas".

The second is a challenge, resounding at the time† when it was written:

"Experiantur itaq., *Vorticum et Pleni absoluti* fautores, an juxta Hypotheses suas poterint hujus Cometæ, per novem integra Signa ac spatium plusquam quadrimestre visi, cursum repræsentare; et an alia Curva, aliave in eâ motus lex a nostra sensibiliter diversa, singularem Viæ ejus Curvaturam, ac Velocitates diversimode auctas ac minutas pari certitudine poterit exhibere. Si hoc fieri nequeat, discant tandem missis nugis Veritatis studio indulgere, et cum Regali Societate nostrâ *Nullius in verba* jurare."

The date predicted by Halley for the first return of the Comet after 1682 was necessarily vague. If perihelion passage about mid-December 1758 be inferred from his language, that would be about three months too early. Since he considered only the effect of Jupiter, and had no means of calculating these perturbations accurately, the result must be considered quite a good one. The subsequent history of the Comet affords an excellent illustration of the development of methods for calculating special perturbations with increasing accuracy.
